[1]Type: C=Concentration, D=Depletion, RM=Reduced Matrix, CS=Covered or Coated Sand Grains. [2]Location: PL=Pore Lining, M=Matrix.

**Hydric Soil Indicators: (Applicable to all LRRs, unless otherwise noted.)**

___ Histosol (A1)
___ Histic Epipedon (A2)
___ Black Histic (A3)
___ Hydrogen Sulfide (A4)
___ Stratified Layers (A5) (**LRR C**)
___ 1 cm Muck (A9) (**LRR D**)
___ Depleted Below Dark Surface (A11)
___ Thick Dark Surface (A12)
___ Sandy Mucky Mineral (S1)
___ Sandy Gleyed Matrix (S4)
___ Sandy Redox (S5)
___ Stripped Matrix (S6)
___ Loamy Mucky Mineral (F1)
___ Loamy Gleyed Matrix (F2)
___ Depleted Matrix (F3)
___ Redox Dark Surface (F6)
___ Depleted Dark Surface (F7)
___ Redox Depressions (F8)
___ Vernal Pools (F9)

**Indicators for Problematic Hydric Soils[3]:**

___ 1 cm Muck (A9) (**LRR C**)
___ 2 cm Muck (A10) (**LRR B**)
___ Reduced Vertic (F18)
___ Red Parent Material (TF2)
___ Other (Explain in Remarks)

[3]Indicators of hydrophytic vegetation and wetland hydrology must be present, unless disturbed or problematic.

**Restrictive Layer (if present):**

Type: ___

Depth (inches): ___

**Hydric Soil Present?** Yes ___ No ✓

Remarks:

## HYDROLOGY

**Wetland Hydrology Indicators:**

Primary Indicators (minimum of one required; check all that apply)

___ Surface Water (A1)
___ High Water Table (A2)
___ Saturation (A3)
___ Water Marks (B1) (**Nonriverine**)
___ Sediment Deposits (B2) (**Nonriverine**)
___ Drift Deposits (B3) (**Nonriverine**)
___ Surface Soil Cracks (B6)
___ Inundation Visible on Aerial Imagery (B7)
___ Water-Stained Leaves (B9)
___ Salt Crust (B11)
___ Biotic Crust (B12)
___ Aquatic Invertebrates (B13)
___ Hydrogen Sulfide Odor (C1)
___ Oxidized Rhizospheres along Living Roots (C3)
___ Presence of Reduced Iron (C4)
___ Recent Iron Reduction in Tilled Soils (C6)
___ Thin Muck Surface (C7)
___ Other (Explain in Remarks)

Secondary Indicators (2 or more required)

___ Water Marks (B1) (**Riverine**)
___ Sediment Deposits (B2) (**Riverine**)
___ Drift Deposits (B3) (**Riverine**)
___ Drainage Patterns (B10)
___ Dry-Season Water Table (C2)
___ Crayfish Burrows (C8)
___ Saturation Visible on Aerial Imagery (C9)
___ Shallow Aquitard (D3)
___ FAC-Neutral Test (D5)

**Field Observations:**

Surface Water Present? Yes ___ No X Depth (inches): ___

Water Table Present? Yes ___ No ✓ Depth (inches): ___

Saturation Present? (includes capillary fringe) Yes ___ No X Depth (inches): ___

**Wetland Hydrology Present?** Yes ___ No ✓

Describe Recorded Data (stream gauge, monitoring well, aerial photos, previous inspections), if available:

Remarks:

# INTRODUCTION

In November 2013 Archaeological Consulting was authorized by Denise Duffy of Denise Duffy & Associates to prepare a CEQA Plus Phase 1 Cultural Resources Survey report for the Monterey Peninsula Groundwater Replenishment Project in northern Monterey County, California.

As part of our methodology in the preparation of this report, we have conducted: 1) a background records search at the Northwest Information Center of the California Historical Resources Information System (CHRIS), located at Sonoma State University; 2) a Sacred Lands File Search through the Native American Heritage Commission (NAHC) and consultation with locally affiliated Native Americans; and 3) a field survey of portions of the project area not previously subject to Archaeological Survey. The following report contains the results of these investigations

# REGULATORY SETTING

This report is prepared to comply with the provisions of the California Environmental Quality Act (CEQA). Under CEQA, a determination must be made whether a project will produce a "potentially significant impact" to the environment. Cultural Resources is one of the environmental factors to be considered when the lead agency for project review makes an environmental impact determination.

## PROJECT DESCRIPTION

The Pure Water Monterey Groundwater Replenishment (GWR) Project is a water resources improvement project proposed by the Monterey Regional Water Pollution Control Agency (MRWPCA) in partnership with the Monterey Peninsula Water Management District (MPWMD). The proposed project would create a reliable source of water supply by injecting highly-treated water from a new advanced water treatment plant into the Seaside Groundwater Basin.

The proposed project consists of two components: 1) the GWR Project components that will develop high quality replacement water for existing urban supplies; and 2) an enhanced agricultural irrigation (Crop Irrigation) component that will increase the amount of recycled water available to the existing Castroville Seawater Intrusion Project (CSIP) in northern Monterey County. Water supplies proposed to be recycled and reused by the project include municipal wastewater, industrial wastewater, urban stormwater runoff and surface water diversions. The proposed project would create a reliable source of water supply by taking highly treated water from new and modified treatment facilities at the Regional Treatment Plant, including a new advanced water treatment (AWT) facility, and injecting it into the Seaside Groundwater Basin using a series of shallow and deep injection wells. Once injected into the Seaside Basin, the treated water would mix with the groundwater present in the aquifers and be stored for future use by CalAm.

## PROJECT LOCATION

The project Area of Potential Effects (APE) includes lands in Marina, Seaside Monterey and Pacific Grove, as well as unincorporated lands north of Marina, south and west of Salinas, and west of Castroville in northern Monterey County, California (see Attachment 1: Maps 1 through 9). The several components of the project include a) source water sites and pipelines, b) treatment facilities at the Regional Treatment Plant (RTP), c) product water conveyance means, d) injection well facilities (see Attachment 1: Figures M-1 through M-21 and M-26), and e) the complementary, but separate, CalAm Distribution System Improvements that consist of the Transfer Pipeline and the Monterey Pipeline (see Attachment 1: Figures M-22 through M-28). The CalAm Distribution System Improvements are being reviewed with regard to archaeological and cultural resources by ESA on behalf of the California Public Utilities Commission, and are not addressed in this report.

The Universal Transverse Mercator Grid (UTMG) coordinates for the approximate ends or centers of the components of the APE are provided below.

**Proposed Source Water Diversion and Storage sites:**

- Tembladero Slough Diversion 6.1022/40.6970 on the USGS 7.5 Minute Moss Landing Quadrangle (1954; photo-revised 1980) (see Figure M-1),
- Salinas Reclamation Ditch Diversion 6.1860/40.6060 on the USGS 7.5 minute Salinas Quadrangle (1947; photo-revised 1984) (see Figure M-2).
- Salinas Pump Station Diversion and Pipeline to the Salinas Industrial Wastewater Treatment Facility (NE 6.1786/40.5800 to SW 6.1606/40.5650 on the USGS 7.5 minute Salinas Quadrangle (1947; photo-revised 1984) (see Figures M-3 and M-4).
- Salinas Industrial Wastewater Treatment Facility. SE 6.1615/40.5636 to NW 6.1410/40.5800 on the USGS 7.5 minute Salinas Quadrangle (1947; photo-revised 1984) (see Figures M-4 and M-5).
- Blanco Drain Diversion Pump Station and Pipeline 6.1210/40.6310 on the USGS 7.5 Minute Salinas Quadrangle (1947; photo-revised 1984) to 6.0990/40.6286 on the Marina Quadrangle (1947; photo-revised 1983) (see Figures M-6 and M-7).

- Lake El Estero 5.9988/40.5075 on the USGS 7.5 Minute Monterey Quadrangle (1947; photo-revised 1983) (see Figure M-26).

**Regional Treatment Plant:** center of the facility 6.1020/40.6300 on the USGS 7.5 Minute Marina Quadrangle (1947; photo-revised 1983) (see Figure M-7).

**Product water conveyance pipeline alignment options:** from the Regional Treatment Plant NW (Coastal) 6.0970/40.6320 or NE (RUWAP) 6.1000/40.6260 on the USGS 7.5 Minute Marina Quadrangle (1947; photo-revised 1983) to 6.0616/40.5338 on the USGS 7.5 Minute Seaside Quadrangle, (1947; photo-revised 1983) (see Figures M-8 through M-21).

**Injection wells and backflush facilities:** from NE 6.0630/40.5350 to S 6.0585/40.5266 on the USGS 7.5 Minute Seaside Quadrangle, (1947; photo-revised 1983) (see Figure M-15).

**Area Of Potential Effects (APE)**

Depending upon the project components, the archaeological APE has been determined as the area of direct impact for the project including areas of ground disturbance, staging areas, access, and work areas. The APE is shown in detail on Figures M-1 through M-21 and M-26 (see Attachment 1). Excavation for pipelines will include an area of direct impact for installation of the pipeline (component footprint) as well as a work area (construction boundary). Because the exact location of some pipelines has not yet been determined, a maximum width (approximately 200 feet) has been delineated as the APE in undeveloped areas. For pipelines installed below existing roadways, the APE is the varying width of the road right-of-way. No excavation or grading will occur in the staging areas; therefore staging area APEs will include the horizontal extent and a minimal depth (less than 6 inches) from potential disturbance relating to the placement and movement of personnel and heavy equipment.

The architectural/structural APE for the project in developed areas includes the area of direct impact and varying width of the road right-of-way (typically 50–75 feet from curb to curb). In the case of project components located in undeveloped areas, the architectural/structural APE is 25 feet from the centerline of the pipeline or a 25-foot buffer from a project component or staging area.

## PROJECT METHODOLOGY

The methodology used in the preparation of this report included three primary steps, as follows:

### Background Research

The background research for this project included an examination of the archaeological site records, maps, and project files of the Northwest Information Center of the California Historical Resources Information System (CHRIS), located at Sonoma State University. In addition, our extensive files and maps were examined for supplemental information, such as unsubstantiated mention of historic or prehistoric resources in the general area. Background literature searches are undertaken to determine the locations of any archaeological resources recorded within or adjacent to the project APE and the scope, methodology and findings of previous archaeological research or reconnaissance studies in and near the APE.

Established by the California Office of Historic Preservation, the regional Information Centers are the local repository for all archaeological reports prepared under cultural resource management regulations. A background literature search at the appropriate Information Center is required by state guidelines and current professional standards. Following completion of a project, a copy of the report must be deposited with that organization.

## Native American Consultation

A Sacred Lands search was initiated with the Native American Heritage Commission (NAHC). Following their search, the commission recommended consultation with locally affiliated Native Americans and provided a list of individuals from several bands to contact for such consultation. Initial contact was initiated by mail or email, followed by telephone or additional email if a timely response was not received.

## Field Survey

Because portions of the APE have been subject to previous archaeological survey, only those areas not previously surveyed were included in the current field study.

On April 3, 2014, Patrick Cave and Gina Kay completed a field survey of the Blanco Drain Diversion pump station and pipeline and segments of the APE for the product water conveyance lines not previously subject to a cultural resources survey. The pedestrian survey consisted of a "general surface reconnaissance" of all parts of the APE that could reasonably be expected to contain visible cultural resources and that could be viewed without major vegetation removal. At the time of our field reconnaissance surface visibility in the undeveloped portions of the APE was generally good. In the developed segment of the Crescent Avenue APE in Marina, visibility adjacent to the roadway was fair. Overall, soil surface visibility was considered adequate for the purposes of this survey.

After receiving unexploded ordnance training Mary Doane and Patrick Cave surveyed the injection wells and backflush facilities portion of the APE located in the former Fort Ord on April 21, 2014. A small portion of that area was surveyed by Patrick Cave in 2012. Visibility in most of the project area was generally fair to poor, partially obscured by coastal scrub including dense patches of poison oak.

Visibility was very good along existing roads and in the southern part of the project area near General Jim Moore Boulevard.

Most of the project APE has been included in previous archaeological surveys and other studies as further described in the next section (see Attachment 2, CHRIS Documentation).

## RESULTS OF THE SURVEY

### Background Research

The project area lies within the currently recognized ethnographic territory of the Costanoan (often called Ohlone) linguistic group. Discussions of this group and their territorial boundaries can be found in Breschini, Haversat, and Hampson (1983), Kroeber (1925), Levy (1978), Margolin (1978), and other sources. In brief, the group followed a general hunting and gathering subsistence pattern with partial dependence on the natural acorn crop. Habitation is considered to have been semi-sedentary and occupation sites can be expected most often at the confluence of streams, other areas of similar topography along streams, or in the vicinity of springs. These original sources of water may no longer be present or adequate. Also, resource gathering and processing areas and associated temporary campsites are frequently found on the coast and in other locations containing resources utilized by the group. Factors that may influence the locations of these sites include the presence of suitable exposures of rock for bedrock mortars or other milling activities, ecotones, the presence of specific resources (oak groves, marshes, quarries, game trails, trade routes, etc.), proximity to water, and the availability of shelter. Temporary camps or other activity areas can also be found along ridges or other travel corridors.

The background search of the files at the Northwest Information Center found recorded cultural resources within or adjacent to several portions of the project APE (see Attachment 2, CHRIS documentation).

Prehistoric midden site CA-MNT-1382/H (P-27-1408) is located near the Tembladero Slough source water APE. Originally recorded south of the intersection of Highway 1 and Merritt Street, the site boundary was expanded to include the sewer pump station in 1989 (Snethcamp and York 1989). Subsequent archaeological testing resulted in remapping of the site boundary to nearly the size and location of the original site record (Jones and Thompson 1992). The current project is not expected to impact this site, based on the corrected site boundary.

Prehistoric site CA-MNT-494 (P-27-0580), recorded by Breschini in 1973 as a slight midden containing several burials, was located within the Salinas Industrial Wastewater Treatment facility. The site was greatly disturbed, if not destroyed by the 1972 grading of the aeration lagoon that unearthed the deposit.

An historic farm site, CA-MNT-2281H (P-27-3057), is recorded near the eastern end of the IWTF north and east of the APE. It will not be impacted by the proposed project.

Several archaeological sites are found around Lake El Estero, a source water location: prehistoric site CA-MNT-955H (P-27-1011) on the hill to the southeast, prehistoric sites CA-MNT-272/304 (P-27-0377), CA-MNT-372 and CA-MNT-373 at the southeast end of the lake, and the National Register listed Royal Presidio Chapel historic site CA-MNT-271 (P-27-0376) above the southwestern end of the lake. None of these recorded sites are within or close to the source water diversion APE on the northern end of Lake El Estero.

Sections of historical fence lines, CA-MNT-2079H (P-27-2416), are adjacent to the northern ends of the Coastal and RUWAP product water conveyance pipeline alignments.

An unremarkable segment of the Monterey and Salinas Valley Railroad Grade, CA-MNT-2080H (P-27-2417), is crossed by the northernmost alignment of the Coastal product water conveyance pipeline. The Monterey and Salinas Valley Railroad Grade has the potential to be a historical resource under CEQA. However, the railroad alignment within the APE exhibits no remaining characteristics of the railroad grade. None of the features or materials associated with the railroad are present in that section of the alignment which has been dramatically modified by activities associated with access roads, the adjacent landfill, fencelines, etc.

West of the Coastal product conveyance line are an historic site at Marina Beach (CA-MNT-1288H (P-27-1325) and several historic structures located in the former Fort Ord (P-27-2881, P-27-2882, P-27-2883, P-27-2884, P-27-2893, P-27-2894, P-27-2895, and P-27-2896). None of these resources will be physically or visually affected by the project.

Most of the project APE has been included in previous archaeological surveys (see Attachment 2, CHRIS Documentation).

Portions of the source water diversion and conveyance APE have been included in the following studies: Tembladero Slough (Peak and Associates 1976; Chavez 1978; Snethcamp 1991; York 1991), Salinas Pump Station Diversion (Weber and Peak 1976), Salinas Reclamation Ditch (Haversat and Breschini 1979), Salinas Industrial Wastewater Treatment facility (Doane and Breschini 2009a, 2009b, 2009c and 2013), Blanco Drain (Bouey 1989), Lake El Estero (Doane and Breschini 2007; Jones and Holson 2009).

The product water conveyance APE through the city of Marina and the Seaside portions of the former Fort Ord has been included in several previous studies (Weber and Peak 1976; Peak and Associates 1978; Runnings and Breschini 1992; Doane and Haversat 1999, 2006; Sawyer et al. 2000; Wilson 2000; Doane 2004; Kirk 2004; Jones and Holson 2009; Ruby 2010; Doane and Breschini 2008 and 2013).

The injection wells and backflush facilities APE have been included in two large studies of the former Fort Ord (Zahnizer and Roberts 1980; Swernoff 1982). The northern portion of the current project APE was field surveyed by Patrick Cave of Archaeological Consulting in 2012 (Doane and Breschini 2012).

**Native American Consultation**

The Native American Heritage Commission Sacred Lands file search found no recorded Sacred Sites in the project APE. Correspondence and consultation with several of the Native Americans recommended by the commission resulted in no additional information about specific resources or sacred sites within the project APE (see Attachment 3, Native American Consultation).

However, several of the consultants had concerns or other comments about the project and its potential impacts. Louise Miranda-Ramirez of the Ohlone/Costanoan-Esselen Nation provided a letter requesting no disturbance of cultural sites and specific follow-up regarding this project (see Attachment 3). Valentin Lopez of the Amah Mutsun Tribal Band declared that, although most of the project APE was out of their traditional territory, he thought any ground disturbance in the vicinity of Tembladero Slough, which is within traditional Mutsun territory, or the Salinas River should be monitored. Ann Marie Sayers of the Indian Canyon Mutsun Band also recommended monitoring of earthwork in the vicinity of Tembladero Slough or other watercourses. Michelle Zimmer and Irenne Zwierlein of Amah/Mutsun Tribal Band had no specific concerns about the project APE but wished to be informed of any new cultural discoveries. Tony Cerda of the Coastanoan Rumsen Carmel Tribe asked to be kept informed of any positive findings of cultural sensitivity in the Monterey area. Follow up messages were left with several others on the contacts list, but no other responses have been received.

**Field Research**

None of the materials frequently associated with prehistoric cultural resources in this area (dark midden soil, marine shell fragments, flaked or ground stone, weathered bone fragments, fire-affected rock, etc.) were observed in any part of the APE covered during the current field survey. The results of previous surveys will be discussed in the conclusions section of this report.

Although the northernmost segment of the Coastal product water conveyance line will pass around the western end of historic fence line CA-MNT-2079H (P-27-2416) and will cross the alignment of the Monterey and Salinas Valley Railroad Grade, CA-MNT-2080H (P-27-2417), no evidence of potentially significant historic resources was noted within the APE during the field survey. The northern segment of the RUWAP product water conveyance line will pass by the eastern section of historic fence line CA-MNT-2079H (P-27-2416). Again no evidence of potentially significant resources was noted during the field survey. No other evidence of potentially significant Historic Period resources, either archival or physical, was found within or adjacent to the project APE.

## CONCLUSIONS AND RECOMMENDATIONS

Based on the background research through the California Historic Resources Information System and the Native American Heritage Commission and based on the findings of our current field survey and previous surveys undertaken within the project APE, we have concluded that there is documentary evidence of cultural resources within or adjacent to portions of the project APE.

The boundary of site CA-MNT-1382/H (P-27-1408) previously included the proposed water source at Tembladero Slough. The archaeological boundary was subsequently redrawn to encompass a smaller area (Snethcamp and York 1991;

Jones et al. 1996). Based on the latest field findings, the project is expected to have no effect on potentially significant historic resources at this location.

The recorded location of prehistoric site CA-MNT-494 (P-27-0580) falls within the Salinas Industrial Wastewater Treatment facility. Based on the original field map location, this prehistoric site was likely damaged, destroyed or buried during development of the facility. No evidence of the archaeological resource has been seen during recent studies within the IWTF (Doane and Breschini 2009a, 2009b and 2009c). No impacts to nearby historic site CA-MNT-2281H (P-27-3057) are anticipated from the project because the recorded resource is north of the eastern end of the IWTF that will not be impacted by the proposed project.

The Coastal product water conveyance line from the RTP would cross the historic Monterey and Salinas Valley Railroad Grade, CA-MNT-2080H (P-27-2417), and skirt the end of historic fence line CA-MNT-2079H (P-27-2416). The RUWAP product water conveyance line would skirt the eastern part of historic fence line CA-MNT-2079H (P-27-2416). No impact to either section of fence line is anticipated with the alignments as proposed. The railroad grade at the point of crossing is visually unremarkable, and appears to have been previously altered by landfill and Regional Wastewater Treatment Plant construction. A segment further south is more apparent in a substantial grade cut through stabilized dunes. Excavation across the railroad alignment is not expected to cause significant impacts to the already substantially altered railroad alignment within the APE.

The remainder of the project, as currently designed, contains no archaeological or historic resources and is expected to have no effect on significant archaeological or historic resources. However, because of the possibility of unidentified (e.g., buried) resources being found during any project involving ground disturbance, we recommend that the following standard language, or the equivalent, be included in any permits issued for the project area:

- If archaeological resources or human remains are unexpectedly discovered during any construction, work shall be halted within 50 meters (±160 feet) of the find until it can be evaluated by a qualified professional archaeologist. If the find is determined to be significant, appropriate mitigation measures shall be formulated, with the concurrence of the Lead Agency, and implemented.

Because of their continuing interest in potential discoveries during construction, all listed Native American Contacts should be notified of any and all discoveries of archaeological resources in the project area.

Re: Monterey Peninsula Groundwater Replenishment Project

Dear Mrs. Imamura:

At your request we initiated a record search of the sacred lands file with the Native American Heritage Commission (NAHC) on March 3, 2014. Attached please find a copy of the response, dated March 6, 2014 from Katie Sanchez of the NAHC. As you will see there was no specific site information found in their files regarding the project area, which lies within traditional Ohlone territory. She recommended that we make additional contacts with other Native American sources of information regarding the potential for cultural resources in the project area. Because these Native American peoples are not a federally recognized tribe, there is no single person or group who represents all of them. A sample copy of the letters regarding your project that were sent on March 6 to the Native American contacts on the NAHC list is also attached.

I have received a letter response from Louise Miranda-Ramirez, Chairperson of the Ohlone/Costanoan-Esselen Nation, requesting information on the resources identified by the CHRIS search. She stresses that her group requests no disturbance of cultural resources. I discussed the project with Val Lopez of the Amah Mutsun Tribal Band, who requested monitoring of earth disturbance in the vicinity of Tembladero Slough and the Salinas River. Michelle Zimmer of Amah/Mutsun Tribal Band of Mission San Juan Bautista. She and her mother Irene Zwierlein recommend that work crews receive cultural sensitivity training when working in the vicinity of identified cultural resources and waterways. In addition, I talked with Anne Marie Sayers of the Indian Canyon Mutsun Band, who recommends archaeological and Native American monitoring of work in close proximity to recorded resources.

I called and left messages with the remainder of the listed Native Americans to call or email me with any information or concerns they might have about the project.

Although the Native Americans offered no additional information specific to sites in the project area, they all wished to know of any significant discoveries during any projects. Because of their concern for the preservation of the cultural resources which comprise their heritage, the listed Native Americans should be informed of the of the discovery of any previously unknown cultural resources which may occur during the course of this project. A continuing sensitivity to their concerns and the inclusion of interested Native Americans in this development will be greatly appreciated by them. I have attached an updated Native American Contacts list.

If I should receive further information or requests for consultation from other Native Americans, I will provide a supplement to this summary letter.

Please feel free to call if you have any further questions or need additional information in this matter.

Yours truly,

Mary Doane

Re: Sacred Lands File search request

Dear Debbie:

We are preparing a Phase I Archaeological Survey for the proposed Monterey Peninsula Groundwater Replenishment Project in Monterey County. The pipelines will run through the cities of Marina, Seaside and Monterey, with some other facilities in parts of Salinas, Castroville and Pacific Grove. We do not yet have the results of the CHRIS search for recorded archaeological sites in the project APE but we are aware of several in the near vicinity of several parts of the proposed project.

We are contacting your office for information on possible Native American Sacred sites or concerns in the project area. Would you please search your Inventory of Sacred Lands to determine whether the project area contains any such resources in Township 13S-15S, Range 2E-1W (see attached maps from the USGS 7.5 Minute Moss Landing, Salinas, Marina, Seaside and Monterey Quads).

We are prepared to contact local Native Americans for their comments on the proposed project area if you will provide us with the names and addresses on your current list for this part of Monterey County.

If you have any questions about this request, please do not hesitate to contact our office.

Yours truly,

Mary Doane

RE: Monterey Peninsula Groundwater Replenishment Project, Monterey County.

Dear Ms. Doane,

A record search of the Native American Heritage Commission (NAHC) *Sacred Lands File* was completed for the area of potential project effect (APE) for the project referenced above. The search indicates the potential of Native American cultural resources in the project vicinity that may be impacted on the *Moss Landing* USGS quadrangle, (T 13S, R 2E, Sec. 18). The site is described as the *Elkhorn Slough*. For specific information regarding this site, please contact the *Ohlone Indians.* The contact information is on the attached *Native American Contacts List.*

The absence of specific site information in the *Sacred Lands File* does not indicate the absence of Native American cultural resources in any APE. Other sources of cultural resources information should be contacted regarding known and recorded sites. Please contact all of the people on the attached list. The list should provide a starting place to locate areas of potential adverse impact within the APE. I suggest you contact all of those listed, if they cannot supply information, they might recommend others with specific knowledge. By contacting all those on the list, your organization will be better able to respond to claims of failure to consult. If a response has not been received within two weeks of notification, the NAHC requests that you follow-up with a telephone call to ensure that the project information has been received

If you receive notification of change of addresses and phone numbers from any of these individuals or groups, please notify me. With your assistance we are able to assure that our lists contain current information. If you have any questions or need additional information, please contact me at my email address: Katy.Sanchez@nahc.ca.gov.

Sincerely,

Katy Sanchez

Re: Monterey Peninsula Groundwater Replenishment Project

Dear Linda:

We are in the process of completing a Phase I Archaeological Survey for the proposed Monterey Peninsula Groundwater Replenishment Project in northern Monterey County, California (see Maps attached). The project involves pipelines between Salinas, Marina, Seaside and Monterey with other features for catchment of water in Salinas, Castroville and Pacific Grove, processing of water in Marina and injection wells in the former Fort Ord.

We have not yet received a result from the Northwest Information Center. We know that there is a site near the Castroville supply point and another near a possible Salinas facility. There are many sites along the shoreline in Pacific Grove and Monterey. Most of the areas on the Seaside and Marina Quads are not expected to be near recorded resources.

We are contacting you for additional information on Native American sites that may be in or near the project area and subject to project impacts.

If you have any questions about this request, please do not hesitate to contact our office.

Yours truly,

Mary Doane

Saleki Atsa,

**Ohlone/Costanoan-Esselen Nation objects to all excavation in known cultural lands, even when they are described as previously disturbed, and/or are deemed to be of no significant archaeological value.**

**Please be aware that despite our objections, disturbance to our ancestral heritage sites continues, therefore we request that a Native American Monitor of Ohlone/Costanoan-Esselen Nation, approved by the OCEN Tribal Council be used within our aboriginal territory.** The OCEN Tribal leadership requests to be contacted with: 1) surveys, 2) subsurface testing, 3) presence/absence testing, 4) mitigation and recovery programs, 5) reburial of any of our ancestral remains, and 6) placement of all cultural items. Please be advised that it is our first priority that our ancestor's remains be protected and undisturbed. We desire that all cultural and sacred items be left with our ancestor on site or where they are discovered. We ask for the respect that is afforded all of our current day deceased, by no other word these burial sites are cemeteries, respect for our ancestors as you would expect respect for your deceased family members in today's cemeteries. **Our definition of respect is no disturbance.**

We are aware that Archaeological Consulting, though requesting our input chooses to work with individuals not representing Ohlone/Costanoan-Esselen Nation though we are the **legal, historical and previously federally recognized** tribal government representative for over BIA documented 600 enrolled members of Esselen, Carmeleno, Monterey Band, Rumsen, Chalon, San Carlos Mission and/or Costanoan Mission Indian descent.

Your statement "We know there is a site near Castroville supply point and another near a possible Salinas facility. There are many sites along the shoreline in Pacific Grove and Monterey. Most of the areas on the Seaside and Marina Quads are not expected to be near recorded resources." The acknowledgement that these ceremonial sites/burial cemeteries exist and are protected by CEQA, OCEN requests, upon response from the Northwest Information Center, that we are contacted with the updated information as to the location of these sites as well as other pertinent information. It is the responsibility of the archaeological firm to verify and acknowledge our sacred and ancestral heritage sites, with your employer so that any adverse impacts to OCEN's sacred sites are not destroyed by development. Please provide us with that information.

Thank you for your attention to this matter; I can be contacted at (408) 629-5189. Nimasianexelpasaleki

Sincerely and Respectfully Yours,

Louise J. Miranda Ramirez, Chairperson
Ohlone/Costanoan-Esselen Nation

Dear Ms. Buhler:

In accordance with your request, we have performed a preliminary geotechnical evaluation for the Environmental Impact Report on the Monterey Peninsula Groundwater Replenishment Project located in Monterey County, California. This report presents our preliminary findings, conclusions and recommendations regarding geotechnical aspects of the project for preliminary planning purposes.

We appreciate the opportunity to be of service on this project. If you have any questions or comments regarding our report, please contact the undersigned at your convenience.

Respectfully submitted,

## 1. SUMMARY OF KEY FINDINGS

A brief summary of our key findings is presented below. More detailed information is presented in the following sections of this report.

- Variable geologic conditions are present within the project area. The project area may be divided into three general geologic regimes; northeastern, central, and southwestern. The northeastern area is comprised predominantly of the alluvial floodplain of the Salinas River. The central area is characterized by elevated rolling hills of wind blown eolian deposits. The geology of the southwestern area is variable and includes the flat coastline west of Canyon del Rey and elevated terrain of the Monterey Peninsula.

- Pipeline construction will vary along the alignments from north to south as the geologic conditions change. The northeastern low-lying areas are anticipated to encounter areas of shallow groundwater and soft soil conditions. The central areas are anticipated to encounter friable dune sands that may cave continuously in some areas. The southwestern areas will vary and may include soft wet soil conditions in canyon areas to difficult excavation in granodiorite.

- The project is located in an area of relatively high seismicity. Some active and potentially active faults do cross the project area. The preferred measure to minimize fault rupture hazards is to locate planned structures away from known fault traces. It may not be feasible or practical, however, to locate planned pipelines away from fault traces. Where pipelines cross known fault traces other measures may be considered depending on the potential risk and damage associated with fault rupture, the relative activity of faulting, and the soil conditions. Potential measures that may be considered include: 1) installation of isolation valves on either side of a pipeline fault crossing to reduce water loss in case of rupture, 2) oversize trench excavation and backfill with select compressible materials, or 3) open channel construction and/or flexible couplings. If damage were to occur to any of the pipelines due to fault rupture, it would amount to a pipe break. A broken pipeline could result in soil washout and sinkholes that could damage nearby non-project facilities or the environment. Locating and repairing damaged pipelines and pumps could require a temporary cessation of operations for a significant period of time.

- There is a strong potential for strong ground shaking, seismically induced soil liquefaction, and dynamic settlement at some locations within the project area. Soil liquefaction may impact some structure sites and pipeline alignments. Geotechnical evaluation of liquefaction potential and dynamic settlement, including subsurface exploration, should be performed during the design phase as required by the appropriate city, county, and state building codes and ordinances. Appropriate measures to protect structures and other improvements including foundation design, excavation, and compaction requirements may be developed based on the site specific geotechnical conditions.

- The project may be impacted by corrosion of ferrous metals or sulfate attack on concrete due to corrosive/deleterious soils. The corrosivity depends on the material type and the proximity to saltwater. In general, clay deposits in the alluvium of the Salinas River Valley, southwestern alluvial areas, or coastal marine areas may constitute a corrosive or deleterious environment. Geotechnical evaluation of corrosive soils, including subsurface exploration, should be performed during the design phase as required by the appropriate city, county, and state building codes and ordinances. Appropriate measures to protect structures and other improvements including selection of construction materials may be developed based on the site specific geotechnical conditions.

- The project may be impacted by expansive soils in locations containing clays including the Salinas River Valley, southwestern alluvial areas, and potential locations containing clayey fills. The expansion characteristics of clayey soils may vary locally and should thus be considered during detailed project design on a site-specific basis. Geotechnical evaluation of expansive soils, including subsurface exploration, should be performed during the design phase as required by the appropriate city, county, and state building codes and ordinances. Appropriate measures to protect structures and other improvements including common grading practices such as soil lime treatment, overexcavation, and compaction requirements may be developed based on the site specific geotechnical conditions.

- Some of the low-lying project components are mapped in a 100-year flood zone (See Section 4.7). Some of the project components in low-lying coastal areas are mapped in a tsunami inundation area (See Section 4.3.1.5). Design of such project components should take these hazards into consideration. Damage to, temporary inundation of, or temporary exposure of the proposed new water supply infrastructure due to flooding or tsunami is not expected to result in a significant risk of loss of life or property.

## 2. INTRODUCTION

In accordance with your request and authorization we have performed a preliminary geotechnical evaluation to be used in the preparation of an Environmental Impact Report (EIR) for the Monterey Peninsula Groundwater Replenishment Project (Proposed Project or GWR Project) located in Monterey County, California (Figure 1). The GWR Project is a water resources improvement project in advanced planning phases by the Monterey Peninsula Water Management District (MPWMD), and the Monterey Regional Water Pollution Control Agency (MRWPCA). The purpose of our services has been to make a preliminary evaluation of the soil and geologic conditions within the Proposed Project source water site areas and to develop preliminary data regarding potential geologic and seismic hazards that may impact the project, as well as geotechnical constraints associated with the design and construction of project improvements.

The Proposed Project consists of two components: the Pure Water Monterey Groundwater Replenishment improvements and operations (GWR Features) that will develop high quality replacement water for existing urban supplies; and an enhanced agricultural irrigation (Crop Irrigation) component that will increase the amount of recycled water available to the existing Castroville Seawater Intrusion Project (CSIP) in northern Monterey County. Water supplies proposed to be recycled and reused by the Proposed Project include municipal wastewater, industrial wastewater, urban stormwater runoff and surface water diversions. The Proposed Project would create a reliable source of water supply by taking highly treated water from new and modified treatment facilities at the Regional Treatment Plant, including a new advanced water treatment (AWT) facility, Brine Mixing Facility, Product Water Pump Station and SVRP Modifications, and injecting it into the Seaside Groundwater Basin using a series of shallow and deep injection wells. The GWR Project is being proposed by the MRWPCA in partnership with the MPWMD. Figure 1 shows the regional location of the study area for the Proposed Project. Once injected into the Seaside Basin, the treated water would mix with the groundwater present in the aquifers and be stored for future use.

The primary purpose of the Proposed Project is to provide 3,500 acre-feet per year (AFY) of high quality replacement water to the Seaside Basin to allow California American Water Company (or CalAm[1]) to extract the same amount for delivery to its customers in the Monterey District Service Area, thereby enabling CalAm to reduce its diversions from the Carmel River system by this same amount. Another purpose of the Proposed Project is to provide additional water to the Regional Treatment Plant that could be by recycled at the existing, tertiary treatment facility, the Salinas Valley Reclamation Plant, and used for crop irrigation using the Castroville Seawater Intrusion Project system.

The areas potentially affected by the GWR project source water sites for EIR purposes extend along the coastline of Monterey Bay from near Castroville approximately 16 miles southwest to Pacific Grove and up to approximately 3 miles inland. Additional areas potentially affected by

[1] CalAm is an investor-owned public utility with approximately 38,500 connections in the Monterey Peninsula area.

the GWR project occur between Salinas and the Salinas River (Figure 1). General study area features are described in Section 4.1.

### 2.1. Project Components

This section describes the physical components of the Proposed Project. The following project components are proposed:

- *Source water diversion and storage sites*– diversion of new source waters to the existing municipal wastewater collection system and conveyance of those waters as municipal wastewater to the Regional Treatment Plant (RTP) to increase availability of secondary-treated wastewater for the Proposed Project. See "GWR Source Water Diversion and Storage" in Figure 2A.

- *Treatment facilities at RTP* – use of existing primary and secondary treatment facilities at the RTP, as well as new pre-treatment, advanced water treatment (AWT), product water stabilization, product water pump station, and concentrate disposal facilities, as well as modifications to the Salinas Valley Reclamation tertiary treatment plant. See "GWR Treatment Facilities" in Figure 2A.

- *Product water conveyance* – new pipelines, booster pump station, appurtenant facilities along one of two optional pipeline alignments to move the product water from the RTP to the Seaside Groundwater Basin injection well facilities. See "GWR Product Water Conveyance" in Figure 2A.

- *Injection well facilities* - new deep injection and vadose zone wells to inject Proposed Project product water into the Seaside Groundwater Basin, backflush facilities, pipelines, electricity/ power distribution facilities, and an electrical/motor control building. See "GWR Injection Wells and Backflush Facility" in Figure 2A.

- *Distribution of groundwater from Seaside Groundwater Basin* – new CalAm distribution system improvements needed to convey extracted groundwater and deliver it to CalAm customers. See "California American Water Distribution System" in Figure 2A. These same CalAm distribution improvements also would be needed if CalAm were to implement the Monterey Peninsula Water Supply Project (CalAm Water Supply Project), which is undergoing separate CEQA review.

Many existing facilities will be utilized to convey new source water to the existing RTP including the Salinas sanitary sewer pump station, MRWPCA's 36-inch sanitary sewer force main, City of Salinas industrial wastewater conveyance and treatment facilities, City of Salinas stormwater conveyance facilities, City of Monterey Lake El Estero and nearby wastewater collection systems, and MRWPCA's Monterey Peninsula interceptor system including pump stations. These existing components are part of the Proposed Project; however the use of these components is not being evaluated for impacts because the usage is part of the existing setting. A schematic of the project components is presented in Figure 2A.

### 2.2. Project Alternatives

The Monterey Peninsula Groundwater Replenishment Project is currently considering alternatives for:

- Alternative source water diversion locations at:
  - Laguna Grande Lake
  - Roberts Lake
  - Navy Lake
  - Bay Avenue Outfall
  - Del Monte Dry Weather Diversion
  - Areas of Special Biological Significance (ASBS) compliance Wet Weather Diversion

Alternative project components are not currently part of the Proposed Project, but are being evaluated as part of this report. The locations of the alternative project components in relation to the proposed and existing project components are illustrated in Figure 2B.

## 3. METHODOLOGY

Our study consisted of a preliminary geotechnical evaluation of the various sites and alignments for preliminary planning purposes. Subsurface exploration has not been performed. Specifically, our evaluation included the following tasks:

- Project coordination, including review of preliminary conceptual plans and participation in conference calls.

- Research and review of readily available geologic and seismic literature pertinent to the study area including geologic maps, regional fault maps, seismic data, and geotechnical reports prepared by Ninyo & Moore or other consultants for the study area vicinity. The reports and documents reviewed for this study are listed in Section 9 of this report.
- Compilation and analysis of the data obtained during our literature review to evaluate potential geologic and seismic hazards that may impact the project and evaluate geotechnical aspects of the project for preliminary design and construction consideration.
- Preparation of this preliminary geotechnical evaluation report presenting our findings, conclusions, and recommendations regarding the geotechnical aspects of the project.

## 4. EXISTING CONDITIONS

The general features, geologic conditions, surface soil erosion characteristics, and faulting and seismic conditions as they currently exist over the project study area, are discussed in the following sections.

### 4.1. General Study Area Features

The study area extends from the Castroville area at the Tembladero Slough southwest to the Pacific Grove area in the Monterey Peninsula, and as far inland as Salinas (Figure 1). The project may be divided into three general areas that have relatively distinct geologic and topographic characteristics. These project areas include a northeastern area, a central area, and a southwestern area. The northeastern area of the project includes a large area of low-lying agricultural fields in the floodplain of the Salinas River. Castroville is located within this area approximately 2 miles from the coast, and Salinas is located within this area approximately 8 miles from the coast. The central portion of the project includes rolling hills extending inland from the coast comprised of wind blown eolian deposits. This area includes the urbanized developments of Seaside, and Marina, as well as the former Fort Ord military base. The southwestern portion of the project area includes rolling hills extending inland generally west of Canyon Del Rey into the Monterey Peninsula. The geologic characteristics and boundaries of the northeastern, central and southwestern areas are discussed further in Section 4.2.1.

### 4.2. Geologic Conditions

The regional geologic setting and the various geologic units encountered with the study area are discussed in the following sections.

#### 4.2.1. Geologic Setting

The project area is located within the Coast Ranges physiographic province which is characterized by a series of northwest-trending mountain ranges and valleys that are generally fault controlled. A regional fault map is presented on Figure 3. The Coast Ranges are chiefly composed of thick Mesozoic- and Cenozoic-age sedimentary strata. The northern and southern parts of the ranges are separated by a depression containing the San Francisco Bay. Faults juxtapose blocks of different origins. The majority of the Monterey area is underlain by the Salinian block, which is generally bounded by the San Andreas fault zone to the northeast and the San Gregorio fault zone to the southwest (Rosenberg, 2001h). The Salinian block is comprised of Mesozoic granitic rock and Paleozoic to Mesozoic meta-sedimentary rock (Norris & Webb, 1990). A series of thick Cretaceous- and Tertiary-age sedimentary strata overly much of the Salinian block, and were deposited during marine transgressions and regressions during this timeframe. Several episodes of volcanism, indicative of crustal extension and normal faulting, also occurred in the region during late Oligocene and Miocene time, and produced extrusive igneous rocks ranging in composition from basalt to rhyolite (Rosenberg, 2001h). During Quaternary time, the region has been uplifted to its current elevation and a combination of tectonic and geomorphic processes have shaped the present landscape, including the exposure of marine terraces, deposition of eolian sand, alluvial deposition, and landsliding.

The project may be divided into three general areas, northeastern, central, and southwestern, that have relatively distinct geologic and topographic characteristics. The northeastern portion extends north of the active Salinas River channel and generally consists of a relatively broad low-lying, alluvial floodplain. The central area of the project consists of eolian deposits that form a zone of moderately elevated, rolling hills extending several miles inland from the coastline and south from the Salinas River channel to Canyon del Rey. The southwestern portion of the project extends generally west along the coastline from the Canyon del Rey into elevated terrain of the Monterey Peninsula, which is the coastal expression of a northwesterly trending mountain range uplifted by faulting. The uplifted peninsula includes a variety of geologic units that includes a core of Cretaceous-age granitic rocks, Tertiary-age sedimentary rocks, Pleistocene-age terrace deposits, landslides and alluvial sediments.

### 4.2.2. Geologic Units

Based on our geologic literature review, the geologic units anticipated within the project study area include fill, alluvium, eolian deposits, terrace deposits, Tertiary-age Monterey Formation, and Cretaceous-age poryphyritic granodiorite of Monterey. The distribution of the various geologic units is shown on the regional geology map in Figure 4 along with the existing and proposed project components. The regional geology map symbols are described on Figure 5. A brief summary of these geologic units and their anticipated engineering characteristics are presented below.

#### *4.2.2.1. Fill*

Artificial fill materials are mapped along the proposed CalAm Monterey and Transfer pipelines in the southwest portion of the project study area. We also anticipate that fill materials will be encountered elsewhere throughout the study area where human alterations to the subsurface have occurred. The thickness of fill deposits varies. Based on our experience we anticipate that the fill materials are generally derived from local natural soils and will be similar to the natural soils as described in the following sections. Fill materials may also include imported materials, construction debris, or other waste products. Documentation of the compaction of the fill materials was not available for review.

#### *4.2.2.2. Alluvium*

Alluvial materials are generally mapped in the northeast and southwest portions of the project study area. Alluvium is generally comprised of unconsolidated sediments deposited in alluvial fans, along active stream and river channels, and in floodplains. Project components in the northeastern area of the project are mapped as being underlain by Holocene-age flood-plain deposits, Holocene basin deposits, Holocene alluvial deposits, and Holocene stream channel deposits (Rosenberg, 2001a). The alluvium in the northeastern area of the project is anticipated to generally consist of interbedded silts, clays, sands, and gravels. The northeastern area is largely agricultural and relatively flat, with relatively poor drainage features. Groundwater is anticipated to be within 10 feet of the ground surface (and shallower) in the low-lying areas. The alluvial materials in the northeastern floodplain area of the project are mapped as having moderate to high liquefaction susceptibility (Rosenberg, 2001d).

Portions of the project components in the southwestern area of the project are mapped as being underlain by Holocene basin deposits and Holocene alluvial deposits (Rosenberg, 2001a). Specifically, the proposed Lake El Estero, alternative Laguna Grande Lake[2], alternative Roberts Lake[2], and alternative Navy Lake[2] source water locations are mapped as being underlain by Holocene basin and alluvial deposits. Also, the proposed CalAm Monterey and Transfer pipelines and alternative ASBS Wet Weather Diversion area[2] are underlain by Holocene alluvial deposits where they intersect drainage courses. Alluvial materials in the southwestern project area are anticipated to be more variable due to the complex geologic conditions and terrain associated with the Monterey Peninsula and may include moist to wet, loose/soft clays, silts, and sands. The alluvial materials in the southwestern area of the project are mapped as having high liquefaction susceptibility (Rosenberg, 2001d).

#### 4.2.2.3. *Eolian Deposits*

The central portion of the project between the Salinas River and Canyon del Rey is mapped as being underlain by Pleistocene-age eolian deposits (Rosenberg, 2001a). Rosenberg (2001g) describes these deposits as being weakly to moderately consolidated, moderately to well-sorted silt and fine- to medium-grained sand deposited in an extensive coastal dune field. Shallow groundwater is not anticipated within the elevated eolian deposits, except for localized low-lying areas along the coastline. The eolian deposits are generally mapped as having low liquefaction susceptibility, except where shallow groundwater may be present in localized low-lying areas (Rosenberg, 2001d). The soil erosion hazard within the eolian deposits in the central portion of the project area is mapped as moderate, except along the coast where the soil erosion hazard is mapped as high (Rosenberg, 2001f). Eolian deposits may also be collapsible. Collapsible soil is broadly defined as loose and cemented soil with low moisture content that is susceptible to a large and sudden reduction in volume upon wetting, with no increase in vertical stress.

#### 4.2.2.4. *Terrace Deposits*

Pleistocene-age coastal terrace deposits are mapped within the southwestern portion of the project (Rosenberg 2001a). Rosenberg (2001g) describes these deposits as semiconsolidated, moderately well-sorted marine sand containing thin, discontinuous gravel-rich layers. These deposits can locally include some terrace surfaces and debris flow deposits resting on terrace surfaces. In general, the liquefaction hazard and landslide seismic hazard are mapped as low in areas underlain by coastal terrace deposits (Rosenberg 2001b & 2001d). The soil erosion hazard is mapped as moderate in areas underlain by coastal terraces (Rosenberg 2001f).

---

[2] Alternative project elements are not currently part of the Proposed Project, but are being evaluated as part of this report.

#### *4.2.2.5. Monterey Formation*

The Tertiary-age Monterey Formation is mapped in the southwestern portion of the project along the southern margins of Lake El Estero (Rosenberg, 2001a). However, we understand that proposed physical facilities and disturbance associated with the Lake El Estero diversion will be limited to the northeastern side of the lake. Based on our review of available literature, we do not anticipate the Monterey Formation will be present within the footprint of the Lake El Estero diversion facilities.

Rosenberg (2001g) describes the Monterey Formation as light brown to white, hard, brittle, and platy siliceous mudstone. Clark (1997) describes this unit as thin-bedded and laminated, light brown to white porcelanite with thin clay partings between the porcelanite beds and with thin interbeds of waxy yellow chert. Bentonite beds are present within the Monterey Formation, which are prone to landsliding in sloped areas.

#### *4.2.2.6. Poryphyritic Granodiorite of Monterey*

The Poryphyritic Granodiorite of Monterey is mapped in the southwestern portion of the project along segments of the proposed CalAm Monterey and Transfer Pipeline and a portion of the alternative ASBS Wet Weather Diversion area[2]. This Cretaceous-age granitic rock is light gray to moderate pink, medium-grained, and contains orthoclase phenocrysts 3 to 10 centimeters long (Clark, 1997).

### 4.3. Faulting and Seismicity

The study site is located in the Coast Ranges geomorphic province of California, an area considered seismically active, as are most areas of California. The Coast Ranges are comprised of a series of parallel, northwest-trending mountain ranges and valleys generally controlled by faults. Faults juxtapose blocks of geologic units of different origins called belts. The Monterey area is located within the Salinian block which is a northwest-trending belt bounded to the east by the San Andreas fault, and to the west by the San Gregorio (Sur) fault (Harden, 1998).

Several active and potentially active faults have been mapped within or close to the study area. As defined by the California Geological Survey (CGS), an "active" fault is one that has exhibited seismic activity or has evidence of fault displacement within Holocene time (roughly during the last 11,000 years). "Potentially active" faults are those which show evidence of displacement during Quaternary time (roughly during the last 1.6 million years), but for which evidence of Holocene movement has not been established. The approximate locations of the major faults in the region and their geographic relationship to the project area are shown on Figure 3 and in greater detail on Figure 6.

The California Geological Survey has designated certain active fault traces as Earthquake Fault Zones under the Alquist-Priolo Special Studies Zone Act of 1972 (CGS, 2007). The study area does not include faults designated as Alquist-Priolo Earthquake Fault Zones. The closest such zoned fault is the San Andreas fault located to the northwest of the project.

Table 1 lists selected nearby principal active and potentially active faults that may impact the Proposed Project and the alternative project areas, the estimated maximum moment magnitude of each fault, and the estimated slip rate for each fault. For Proposed Project components, the maximum distances to each fault are based on estimated distances from the southwestern end of the proposed CalAm Distribution System, the Tembladero Slough diversion site, or the Reclamation Ditch diversion site. For alternative project areas, the distances to each fault are based on estimated distances from the Bay Avenue Outfall alternative source water area[2] or the alternative ASBS Wet Weather Diversion area[2].

**Table 1 – Principal Active and Potentially Active Faults**

| Fault | Fault to Proposed Project Area Distance (Range in Miles) | Fault to Alternative Project Areas Distance (Range in Miles) | Maximum Moment Magnitude (Mmax)[1] | Slip Rate (mm/yr)[2] |
|---|---|---|---|---|
| Monterey Bay – Tularcitos Fault Zone | 0-11 | 0-3 | 7.3 | 0.5 |
| Rinconada Fault Zone | 0-7.5 | 6-8 | 7.5 | 1.0 |
| San Andreas (Santa Cruz Mtn Section) | 12-26 | 23.5-25 | 7.0 | 17.0 |

1 Cao, 2003
2 Wills et. al, 2008

The Reliz fault zone is the northward extension of the Rinconada fault zone which trends to the northwest along the base of the mountains at the southwest side of the Salinas River valley. The northernmost known indication of Quaternary movement along this fault zone is the steeply dipping Paso Robles Formation beds near the Spreckels area (Rosenberg, 2001f). The Reliz fault has been projected northwest from Spreckels crossing through the central portion of the project area in the Marina vicinity (Jennings and Bryant, 2010; Rosenberg, 2001c). This portion of the fault passes beneath eolian deposits and the location is uncertain. This fault system has displaced materials of late Quaternary age (11,000 to 750,000 years old) and is considered potentially active (Rosenberg, 2001c).

The Monterey Bay-Tularcitos fault zone crosses through the Monterey-Seaside area and extends offshore (Clark et al., 1997). The onshore portion in the project vicinity includes the Ord Terrace, Seaside, Chupines, and Navy faults. These faults create an approximately 5 to 9 mile wide zone of short en echelon northwest-striking faults that are genetically related. The activity and locations of these faults are not well defined. Geologic data indicates Holocene displacement at some locations and these faults should be considered active for planning purposes.

The northernmost Ord Terrace fault is mapped beneath eolian deposits in the central portion of the project area through the proposed CalAm Monterey and Transfer Pipelines and near the proposed GWR Injection Well Facilities (Figure 6). The Ord Terrace fault is a steeply southwest-dipping reverse fault. There is evidence for Pleistocene activity in the northward extension of the fault into Monterey Bay, where it cuts Pleistocene strata and offsets the sea floor (Rosenberg, 2001h). Rosenberg (2001c) shows displacement on the Ord Terrace fault within Quaternary time but prior to the middle Pleistocene (Figure 6).

The Seaside fault is mapped beneath eolian deposits through the proposed CalAm Monterey and Transfer pipelines in the central portion of the project area. The Seaside fault is a steeply southwest-dipping reverse fault and well data suggests that its trace connects to a splinter of the Chupines fault near Highway 68. Well logs on either side of the fault show an approximate 275 foot vertical offset of Pleistocene continental deposits, but evidence for Holocene movement is lacking (Rosenberg, 2001h). Rosenberg (2001c) shows displacement along the Seaside fault within Quaternary time but prior to the middle Pleistocene (Figure 6).

The Chupines fault is mapped to the northeast of the Roberts Lake and Laguna Grande Lake through the proposed CalAm Monterey pipeline within the southwestern edge of the central portion of the project area. At locations where the fault orientation is measurable, its dip ranges from 50 degrees southwest to near-vertical. A probable offshore extension of the Chupines fault cuts Holocene deposits and seafloor deposits (Rosenberg, 2001h). Thus the portion of the fault within the project area is considered active.

The Navy fault is mapped to the southwest of Navy Lake through the proposed CalAm Monterey Pipeline within the southwestern portion of the project area. Its northwest-striking alignment is consistent with the Tularcitos fault zone and extends from Carmel Valley to Monterey Bay. The Navy fault dips steeply to the southwest and geomorphic features along its trace such as linear drainages and aligned benches indicate predominantly strike-slip movement. Clark (1997) reports Holocene activity on the Navy fault based on Holocene displacements of offshore strata and earthquake epicenter plots near the fault trace. Rosenberg (2001c) however shows displacement within Quaternary time but prior to the middle

Pleistocene. The Fault Activity Map of California (Jennings & Bryant, 2010) indicates that displacement along the onshore portion of the Navy fault within the study area dates to late Quaternary and pre-Holocene time.

### 4.3.1. Seismic Hazards

Seismic hazards that could potentially affect improvements within the study area include surface fault rupture, ground shaking, soil liquefaction and dynamic settlement, lateral spreading, tsunamis and landsliding. Seismic hazards associated with the Proposed Project and project alternatives are discussed in the following sections.

#### *4.3.1.1. Fault Rupture*

Evaluation of fault rupture hazard is based on the concepts of recency and recurrence of faulting along existing faults. Faults of known historic activity during the last 200 years, as a class, have a greater probability for future activity than faults classified as Holocene age (last 11,000 years), and a much greater probability of future activity than faults classified as Quaternary age (last 1.6 million years). However, it should be kept in mind that certain faults have recurrent activity measured in tens or hundreds of years whereas other faults may be inactive for thousands of years before being reactivated. The magnitude, sense, and nature of fault rupture also vary for different faults or along different strands of the same fault. Even so, future faulting generally is expected to recur along pre-existing faults (Bonilla, 1970). The development of a new fault or reactivation of a long-inactive fault is relatively uncommon.

Faults in the vicinity of the project have demonstrated Quaternary movement and can be considered at least potentially active (Figures 6A & 6B). The Chupines fault, the Navy fault, and the Seaside Fault have demonstrated Holocene movement and can be considered active. Based on our review of the project plans and geologic maps, these faults cross the proposed CalAm Monterey Pipeline. As such, there is potential for fault rupture within the project area.

The Reliz, Chupines, and Navy faults cross the proposed CalAm Monterey Pipeline. The Ord Terrace fault potentially crosses the CalAm Monterey Pipeline and traces very near the proposed GWR Injection Well Facilities. These faults have shown evidence of displacement within Quaternary time but have not shown displacement within Holocene time. The approximate location of these faults and their geographic relationship to the proposed improvements are shown on Figure 6.

#### *4.3.1.2. Ground Shaking*

Strong ground shaking may occur due to earthquake events along active faults nearby or distant to the study area. Disregarding local variations in ground conditions, the intensity of shaking at different locations within the area can generally be expected to decrease with distance away from an earthquake source. Measurements of peak ground acceleration, in units of g, may be used for quantification of shaking intensity. In general, peak ground accelerations of less than 0.10g are indicative of weak shaking, values between 0.10g and 0.20g are indicative of moderate shaking, and values over 0.20g are indicative of strong shaking. The shaking intensity due to an earthquake felt at any given site depends on the shear wave velocity properties of the soil or rock conditions at that site. The California Geologic Survey Ground Motion Interpolator (CGS, 2008) based on the 2008 Probalistic Seismic Hazard Assessment by the United States Geological Survey (Petersen et al, 2008), indicates that the peak ground acceleration with a 2 percent chance of being exceeded in 50 years ranges between 0.60g and 0.65g over the study area for an assumed shear wave velocity of 270 meters per second, which is representative of a site underlain by stiff soil.

#### *4.3.1.3. Soil Liquefaction and Dynamic Settlement*

Liquefaction is a phenomenon in which soil loses its shear strength for short periods of time during an earthquake. Ground shaking of sufficient duration results in the loss of grain-to-grain contact, due to a rapid increase in pore water pressure, causing the soil to behave as a fluid for short periods of time. The potential damaging effects of liquefaction include differential settlement, loss of ground support for foundations, ground cracking, heaving and cracking of structure slabs due to sand boiling, and buckling of deep foundations due to liquefaction-induced ground settlement. Dynamic settlement may also occur in loose, dry sands above the water table.

In general, a relatively high potential for liquefaction exists in loose, sandy soils that are within 50 feet of the ground surface and are saturated (below the groundwater table). Some locations within the project study area, including the floodplain of the Salinas River, low-lying coastal areas, and alluvial river-bottom areas such as Canyon del Rey (Highway 68) and other drainages within the southwestern portion of the project have a moderate to high liquefaction potential (Figure 7). Separate locations of historical liquefaction incidents have been documented within the project area, the majority of which were located within the northeastern project area (Figure 7). There may be a moderate potential for dynamic settlement of dry, loose sands within the elevated dune sand deposits.

#### *4.3.1.4. Lateral Spreading*

Lateral spreading is horizontal earth movement associated with soil liquefaction. Lateral spreading generally occurs in shallow ground water areas with unsupported embankments including natural creek banks, fill slopes, levees, etc. Areas that have a potential for lateral spreading within the study area are low-lying areas near river channels, sloughs, or other drainages.

#### *4.3.1.5. Tsunami*

Tsunamis are open sea tidal waves generated by earthquakes. Tsunami damage is typically confined to low-lying coastal areas. Project components along the low-lying coastal areas may be impacted by tsunamis. A majority of the coastline along

Monterey Bay is mapped within a tsunami inundation area (Figure 10), which includes some project components. Portions of the proposed CalAm Monterey Pipeline, the area within and around the proposed Lake El Estero, Tembladero Slough, and Blanco Drain source water locations are mapped within a tsunami inundation zone. The alternative source water locations[2] at Navy Lake, Roberts Lake, Laguna Grande Lake, and Bay Avenue are mapped within a tsunami inundation zone (CGS, 2009a,b,c).

##### *4.3.1.6. Earthquake-Induced Landslides*

Landslides initiated by earthquakes have historically been a major cause of earthquake damage. Landslides initiated by the 1971 San Fernando, 1989 Loma Prieta and 1994 Northridge earthquakes were responsible for destroying or damaging numerous homes and other structures, blocking major transportation corridors, and damaging various types of lifeline infrastructure. Seismically induced landsliding includes surficial sliding/rock falls and deep seated landsliding. Relatively shallow surficial sliding may occur throughout the project area where steep slope gradients are present and/or loose soil conditions exist (such as eolian sands, loose topsoil, and fill slopes). The relative potential for earthquake induced landslides within the project study area is presented in Figure 8. The project study area is generally considered to be in an area of low susceptibility to earthquake-induced landsliding (Rosenberg, 2001b).

### 4.4. Surface Soil Erosion

Surface soils tend to erode under the wearing action of flowing water, waves, wind, and gravity. Factors influencing erosion include topography, soil type, precipitation and other environmental conditions. In general, granular soils with relatively low cohesion and soils located on relatively steep topography have relatively high erosion potential. Within the project area, coastal areas north of Lake El Estero and the slopes on the southern side of the Salinas River have a high potential for erosion (Rosenberg, 2001f). The coastal terrace and eolian deposits inland from the coastline with less steep topography are considered to have a moderate potential for erosion. The relatively flat areas within the Salinas River valley have a low potential for erosion.

Coastal erosion in the Southern Monterey Bay is expected to increase with accelerating sea level rise. As the sea level rises over the next century and beyond, some of the project components may be affected during major storm events by wave run-up into dune areas and subsequent undercutting at the dune toe, causing increased erosion. A memorandum prepared by ESA PWA, 2014, shows selected coastal zones at risk of damage during a major storm event, considering sea level rise scenarios through 2060. The memorandum includes a longitudinal profile spanning between Lake El Estero and Monterey Bay, with the approximate location of the proposed CalAm Monterey Pipeline plotted within the envelope of erosion for a 100-year storm considering predicted sea levels in 2040 and 2060. Coastal areas significantly east and west of the above longitudinal profile location are not specifically analyzed in the memorandum, however it is possible that coastal erosion exacerbated by sea level rise may affect nearby project components.

The project may include earthwork for the construction of project improvements, including trenching for pipelines and miscellaneous excavations. Disturbed areas will have a relatively high potential for erosion. Standard construction practices to mitigate erosion include preparation of a Storm Water Pollution Prevention Plan (SWPPP). The SWPPP includes construction best management practice measures such as desilting basins, silt fences, hydroseeding of slopes, and monitoring and clean-up requirements. Erosion control plans prepared and designed by the project civil engineer are recommended. Long term best management practice measures may include vegetating graded slopes, design of appropriate drainage control systems and suitable drainage outlets.

### 4.5. Expansive Soils

Some clay minerals undergo volume changes upon wetting or drying. Unsaturated soils containing those minerals will shrink/swell with the removal/addition of water. The heaving pressures associated with this expansion can damage structures, flatwork, and pipelines. Clayey soils may be encountered throughout the project area in fill, alluvial, and formational materials. The expansion characteristics of clayey soils may vary locally and should thus be evaluated on a site-specific basis. Such an evaluation may include laboratory testing.

### 4.6. Collapse Potential

Collapsible soil is broadly defined as loose and cemented soil with low moisture content that is susceptible to a large and sudden reduction in volume upon wetting, with no increase in vertical stress. The process of soil collapse upon wetting is referred to as hydrocollapse. Another type of collapse can occur in saturated soil bearing soluble minerals when subjected to continuous leaching. Some common soluble soil minerals include calcium chloride, magnesium chloride, sodium chloride, potassium chloride, gypsum, anhydrite, dolomite, and calcium carbonate (Mansour, 2008). The composition of minerals dissolved in leaching water will affect the soil mineral dissolution rate.

The most common types of collapsible soil include alluvial soils, eolian deposits, and residual soils formed by extensive weathering of parent materials such as granitic rock (Mansour, 2008). Within the project area alluvial materials, eolian deposits, and residual soil over granodiorite are present. Settlement may occur where these materials are loose, relatively dry, and subjected to a significant increase in moisture content. A site-specific evaluation of collapse potential and resulting settlement should be performed in these materials where saturation of the soil or a substantial rise in groundwater levels above the historic highs are anticipated.

### 4.7. Flooding

Our review of flood mapping by the Monterey County Resource Management Agency (2010) found that some of the project area is within a 100 year flood zone. A majority of the coastline along Monterey Bay is mapped within a 100 year flood zone (Figure 11), which includes some project components such as portions of the proposed CalAm, Monterey and Transfer pipelines and the Bay Avenue alternative source water location[2]. In the southwestern part of the project area, the areas within and around the proposed Lake El Estero source water location, and alternative source water locations[2] at Navy Lake, Roberts Lake, and Laguna Grande Lake are mapped within the 100 year flood zone. In the central part of the project area, there are sporadic zones within the vicinity of Marina and north of Seaside that are mapped within the 100 year flood zone. In the northeastern part of the project area, a majority of the Salinas River floodplain and Tembladero Slough vicinity is mapped within the 100 year flood zone.

## 5. PROJECT IMPACT ANALYSIS

The following sections discuss the impacts that the existing/anticipated geotechnical, geologic, and seismic conditions might have on the construction and performance of the proposed project. Each project element will be discussed in turn. Detailed design information regarding many of the project components is not yet available.

### 5.1. Proposed GWR Injection Wells and Backflush Facilitiy

It is our understanding that the proposed project includes the construction of an Injection Well Facility, which will include both deep injection wells into the confined Santa Margarita Aquifer and vadose zone wells to recharge the shallower Paso Robles Aquifer, as well as monitoring wells, a backflush basin, pipelines, and operations buildings. The location considered for this site is east of Seaside, along the eastern side of General Jim Moore Boulevard and south of Eucalyptus Road (Figure 2A). Elevations at this proposed site range from approximately 330 to 425 feet above mean sea level (MSL). This location is underlain by eolian deposits that are anticipated to consist of weakly to moderately consolidated, moderately to well-sorted silt and fine- to medium-grained sand. Groundwater is expected to be relatively deep; around 400 feet below the ground surface.

There are potential geologic hazards and considerations associated with the use of this site as an Injection Well Facility. The surface trace of the Ord Terrace Fault is mapped approximately ¼ mile southwest of this site; however the location of this fault within the

Pleistocene eolian deposits is not well-defined. The Ord Terrace fault is considered potentially active but dips steeply toward the southwest away from the site (Rosenberg 2001h),thus minimizing exposure of Injection Well Facilities to fault rupture.

The eolian deposits that underlie the proposed location for the Injection Well Facilities may be susceptible to hydro-collapse that would result in ground subsidence if large quantities of water are injected into the ground above historic high groundwater levels. However, we understand that the proposed vadose zone wells are designed to reach depths of 100 to 200 feet, so wetting of the eolian deposits would occur at 100 feet or deeper, and mounding beneath the vadose zone wells is not expected to be significant. Based on this scenario, we consider the potential for hydrocollapse due to the vadose zone injection wells to be negligible. We also understand that the proposed back-flush basin may cause wetting of the shallow eolian deposits. However, the back-flush basin is only expected to receive pumped water for a few hours per week so settlement due to hydrocollapse is anticipated to be relatively minor and limited to the footprint of the back-flush basin which can accommodate minor settlement. As such, we do not consider the impact of hydrocollapse resulting from use of the back-flush basin to be significant.

## 5.2. Water Collection, Conveyance, Distribution, and Storage Alignments

The existing and proposed project components are illustrated in Figure 2A. The alternative project components are illustrated in Figure 2B. As discussed in Section 4.2.1, the project study area may be divided into three general regions with relatively distinct geologic and topographic characteristics. In the following sections, we will address the potential impacts that the proposed project and alternative components experience in each of the three general areas: northeastern, central, and southwestern.

### 5.2.1. Northeastern Area

The northeastern area contains proposed project components including the Salinas Treatment Facility, the Salinas Pump Station, Tembladero Slough, Reclamation Ditch , and the eastern portion of the Blanco Drain source water diversion site. The Blanco

Drain source water site will require a new pipeline for connection to the RTP in the central project area.

The northeastern area includes low-lying, relatively flat, alluvial plains of the Salinas River valley and the relatively narrow flood plains of the Tembladero Slough. Ground surface elevations in the Salinas River valley area of the project generally range from approximately 10 to 45 feet above MSL. Ground surface elevations near the Tembladero Slough source water site[2] range from approximately 4 to 10 feet above MSL. The northeastern area is generally developed with agricultural fields, industrial facilities, and some mixed residential/commercial development in Salinas and Castroville.

The low-lying floodplain areas are underlain by Holocene alluvial deposits. These deposits include unconsolidated interbedded silts, clays, sands, and gravels. Groundwater is anticipated to be approximately 10 feet deep or less in low-lying areas. Drainage conditions are relatively poor and the subsurface is anticipated to consist of moist to saturated soils. Trench excavations may encounter groundwater, moist to wet soils, and soft ground conditions. Trench dewatering may be required. Moist to wet soil conditions along lower elevations may require drying/mixing prior to trench backfill compaction. Soft ground may require overexcavation and stabilization with crushed rock/filter fabric to provide suitable pipe bedding support. The liquefaction susceptibility in low-lying flood plain areas is moderate to high. Clayey soils are potentially corrosive and/or expansive.

#### 5.2.2. Central Area

The central portion of the study area includes the proposed GWR product water conveyance alignments, the eastern portion of the proposed CalAm Monterey and Transfer pipelines, the proposed GWR Injection Well Facility, and the western portion of the Blanco Drain source water diversion site. The Blanco Drain source water will require a new pipeline for connection to the RTP. The central area also contains several site locations considered as alternative project components[2] for supplemental source water.

including the Bay Avenue alternative outfall site and the Del Monte Boulevard Dry Weather Diversion site.

This central area includes gently to moderately rolling dunes with elevations ranging from approximately 10 feet above MSL near the Salinas River to approximately 350 feet above MSL along southernmost portion of the proposed GWR product water conveyance alignment. The project components in this area traverse agricultural fields, undeveloped areas, and residential, commercial, and military developments.

Trenching for pipelines in the central area will generally encounter eolian deposits and fill materials. The eolian deposits are anticipated to consist of weakly to moderately consolidated, moderately to well-sorted silt and fine- to medium-grained sand. Fill materials are generally anticipated to consist of compacted silts and sands generated locally from the natural eolian deposits. Fill materials may also include imported soils and miscellaneous debris (particularly in older developed areas and along the former Fort Ord military base). We generally anticipate well-drained conditions and relatively deep groundwater, although shallow groundwater may be present along low-lying coastal areas. Trenching conditions can vary depending on presence/absence of cementation and/or groundwater. Excavations in eolian deposits may encounter flowing sands and caving. Temporary construction slopes may range up to 1.5:1 or 3:1 (horizontal:vertical) inclinations. Continuous shoring may be appropriate to protect existing improvements, where temporary slopes are not feasible. Flowing sand conditions may warrant special excavation and shoring procedures to protect adjacent improvements and existing utilities, such as trench shields placed during excavation and limited open trench conditions. Sandy materials should be suitable for trench zone and trench backfill. The susceptibility to liquefaction is considered low, except in low-lying coastal areas. Dynamic settlement of loose dry sands may be a potential hazard to pipelines. Sands are anticipated to have low corrosivity potential and moderate to high potential for erosion. The Reliz fault has been projected across the proposed pipeline alignments near Marina. Similarly, the Chupines, Seaside and Ord Terrace faults have been traced across the proposed alignments near Seaside and Del Rey Oaks. As such there is potential that rupture along these faults may impact the pipelines at these locations.

### 5.2.3. Southwestern Area

The southwestern portion of the study area includes the western portion of the proposed CalAm Monterey and Transfer pipelines and the Lake El Estero source water site.

The southwestern area also contains several site locations considered as alternative project components[2] for supplemental source water, including the Laguna Grande Lake alternative source water diversion site, the Roberts Lake alternative source water diversion site, the Navy Lake alternative source water diversion site, and the ASBS Wet Weather Diversion area.

The topography in the southwestern area is variable and includes the relatively low-lying coastal area between Canyon del Rey and Lake El Estero, gently sloping terraces beginning several blocks west of Lake El Estero and inland, and undulating coastal bluffs on portions of the coastline. Elevations range from approximately 10 feet above MSL between Canyon Del Rey and Lake El Estero to approximately 220 feet above MSL at the western terminus of the proposed CalAm Monterey Pipeline. The project components span park areas, commercial developments, and residential developments.

Variable geologic conditions are present within the southwestern area, including fill materials, Holocene-age alluvial materials, Pleistocene-age coastal terraces, Tertiary-age Monterey Formation, and Cretaceous-age Porphyritic granodiorite of Monterey. It is anticipated that the fill materials are generally derived from local natural soils and will be similar to the natural soils. Fill materials may also include imported materials, construction debris, or other waste products. Alluvium along canyon bottoms and drainages is anticipated to include moist to wet, loose/soft clays, silts, and sands. Shallow groundwater may be encountered along lower canyon and drainage areas. Flat and sloped areas throughout the southwestern portion of the study area contain coastal terrace deposits anticipated to be comprised of semi-consolidated, moderately well-sorted marine sand containing thin, discontinuous gravel-rich layers. The southwestern edge of Lake El Estero is mapped as being underlain by the Monterey Formation. The western portion of the proposed CalAm Monterey Pipeline is anticipated to encounter granodiorite in several locations.

Trench excavations in the low-lying alluvial areas may encounter some soft, wet, alluvium with a potential for caving and unstable trench bottoms. Dewatering may be required. Moist to wet soil conditions along lower elevations may require drying/mixing prior to trench backfill compaction. Soft ground may require overexcavation and stabilization with crushed rock/filter fabric to provide suitable pipe bedding support. Low-lying alluvial areas may be considered to have a relatively high susceptibility to liquefaction and dynamic settlement. Trenches excavated in coastal terrace deposits may experience variable stability due to potential zones where debris flow deposits locally overlie the terrace deposits. Monterey Formation and granodiorite materials are anticipated to be relatively stable in trench excavations. Difficult excavating may be encountered in granodiorite and strongly cemented layers of the Monterey Formation. Specialized excavation equipment, such as ripper teeth or chipper attachments may be appropriate for trenching in these deposits. The materials generated from trench excavations in the southern area will vary and are not anticipated to be suitable for use as pipe zone material. Imported sand should be used for backfill around pipes. The majority of excavated material should be suitable for trench backfill, but oversize rock fragments from hard rock areas may be unsuitable.

The proposed CalAm Monterey Pipeline in the City of Monterey crosses a mapped trace of the Navy fault. Additionally, project components underlain by fill or alluvium may have high liquefaction susceptibility. Soil erosion hazards within this area range from low to high. Subsequent geotechnical evaluations within these areas of the project should further evaluate potential liquefaction and fault rupture hazards.

## 6. PRELIMINARY CONCLUSIONS AND RECOMMENDATIONS

The purpose of our preliminary geotechnical services has been to evaluate the soil and geologic conditions within the project area and to develop preliminary data regarding geologic and seismic hazards and geotechnical constraints that may impact the project. To accomplish this we have reviewed geologic and seismic background data of the current Proposed Project and alternative project components. Detailed design information regarding most of the project components is not available yet. Based on the results of our preliminary evaluation, it is our opinion that the project is feasible from a geotechnical perspective, provided appropriate design, engineering and construction considerations are incorporated into the project. This report has been prepared for use in the preliminary planning of the project. Prior to design of facilities geotechnical evaluations should be performed to prepare appropriate geotechnical design criteria for pipeline alignments and sites, as required by the appropriate city, county, and state building codes and ordinances. A summary of our preliminary findings and recommendations is presented below.

- Variable geologic conditions are present within the project area. The project area may be divided into three general geologic regimes; northeastern, central, and southwestern. The northeastern area is comprised predominantly of the alluvial floodplain of the Salinas River. The central area is characterized by elevated rolling hills of wind blown eolian deposits. The geology of the southwestern area is variable and includes the flat coastline west of Canyon del Rey and elevated terrain of the Monterey Peninsula.

- Pipeline construction will vary along the alignments from north to south as the geologic conditions change. The northeastern low-lying areas are anticipated to encounter areas of shallow groundwater and soft soil conditions. The central areas are anticipated to encounter friable dune sands that may cave continuously in some areas. The southwestern areas will vary and may include soft wet soil conditions in canyon areas to difficult excavation in granodiorite.

- The project is located in an area of relatively high seismicity. Some active and potentially active faults do cross the project area. The preferred measure to minimize fault rupture hazards is to locate planned structures away from known fault traces. It may not be feasible or practical, however, to locate planned pipelines away from fault traces. Where pipelines cross known fault traces other measures may be considered depending on the potential risk and damage associated with fault rupture, the relative activity of faulting, and the soil conditions. Potential measures that may be considered include: 1) installation of isolation valves on either side of a pipeline fault crossing to reduce water loss in case of rupture, 2) oversize trench excavation and backfill with select compressible materials, or 3) open channel construction and/or flexible couplings. If damage were to occur to any of the pipelines due to fault rupture, it would amount to a pipe break. A broken pipeline could result in soil washout and sinkholes that could damage nearby non-project facilities or the environment. Locating and repairing damaged pipelines and pumps could require a temporary cessation of operations for a significant period of time.

- There is a strong potential for strong ground shaking, seismically induced soil liquefaction, and dynamic settlement at some locations within the project area. Soil liquefaction may impact some structure sites and pipeline alignments. Geotechnical evaluation of liquefaction potential and dynamic settlement, including subsurface exploration, should be performed during the design phase as required by the appropriate city, county, and state building codes and ordinances. Appropriate measures to protect structures and other improvements including foundation design, excavation, and compaction requirements may be developed based on the site specific geotechnical conditions.

- The project may be impacted by corrosion of ferrous metals or sulfate attack on concrete due to corrosive/deleterious soils. The corrosivity depends on the material type and the proximity to saltwater. In general, clay deposits in the alluvium of the Salinas River Valley, southwestern alluvial areas, or coastal marine areas may constitute a corrosive or deleterious environment. Geotechnical evaluation of corrosive soils, including subsurface exploration, should be performed during the design phase as required by the appropriate city, county, and state building codes and ordinances. Appropriate measures to protect structures and other improvements including selection of construction materials may be developed based on the site specific geotechnical conditions.

- The project may be impacted by expansive soils in locations containing clays including the Salinas River Valley, southwestern alluvial areas, and potential locations containing clayey fills. The expansion characteristics of clayey soils may vary locally and should thus be considered during detailed project design on a site-specific basis. Geotechnical evaluation of expansive soils, including subsurface exploration, should be performed during the design phase as required by the appropriate city, county, and state building codes and ordinances. Appropriate measures to protect structures and other improvements including common grading practices such as soil lime treatment, overexcavation, and compaction requirements may be developed based on the site specific geotechnical conditions.

- Some of the low-lying project components are mapped in a 100-year flood zone (See Section 4.7). Some of the project components in low-lying coastal areas are mapped in a tsunami inundation area (See Section 4.3.1.5). Design of such project components should take these hazards into consideration. Damage to, temporary inundation of, or temporary exposure of the proposed new water supply infrastructure due to flooding or tsunami is not expected to result in a significant risk of loss of life or property.

## 7. FUTURE WORK

Detailed site-specific geotechnical engineering studies including subsurface exploration and laboratory testing should be performed during future design phases of the project, as required by the appropriate city, county, and state building codes and ordinances to identify engineering and geotechnical design criteria related to liquefaction potential, fault surface rupture, or other geotechnical constraints at the specific sites so that appropriate geotechnical design and construction recommendations can be prepared. Subsurface exploration may also be considered to provide additional data for selection of alternative sites. The recommendations developed as part of the final geotechnical study would provide the engineering and construction design details related to seismic design considerations, foundation design, excavation characteristics, and backfill requirements. Design measures may include foundation parameters, removal of problematic soils, compaction requirements, pipe bedding requirements, and special trench backfill requirements that represent standard engineering practices typically utilized for infrastructure and pipeline projects.

## 8. LIMITATIONS

The desktop evaluation and geotechnical analyses presented in this geotechnical report have been conducted in general accordance with current practice and the standard of care exercised by geotechnical consultants performing similar tasks in the project area. No warranty, expressed or implied, is made regarding the conclusions, recommendations, and opinions presented in this report. Conditions not described in this report may be encountered during subsurface exploration and construction. Uncertainties relative to subsurface conditions can be reduced through subsurface exploration. Please also note that our evaluation was limited to assessment of the geotechnical aspects of the project, and did not include evaluation of structural issues, environmental concerns, or the presence of hazardous materials.

This document is intended to be used only in its entirety. No portion of the document, by itself, is designed to completely represent any aspect of the project described herein. Ninyo & Moore should be contacted if the reader requires additional information or has questions regarding the content, interpretations presented, or completeness of this document.

This report is intended for preliminary planning purposes only. A detailed geotechnical evaluation, including subsurface exploration should be performed prior to detailed design and construction.

Our conclusions, recommendations, and opinions are based on a review of preliminary conceptual plans and geologic and seismic literature. If geotechnical conditions different from those described in this report are encountered, our office should be notified and additional recommendations, if warranted, will be provided upon request. It should be understood that the conditions of a site could change with time as a result of natural processes or the activities of man at the subject site or nearby sites. In addition, changes to the applicable laws, regulations, codes, and standards of practice may occur due to government action or the broadening of knowledge. The findings of this report may, therefore, be invalidated over time, in part or in whole, by changes over which Ninyo & Moore has no control.

This report is intended exclusively for use by the client. Any use or reuse of the findings, conclusions, and/or recommendations of this report by parties other than the client is undertaken at said parties' sole risk.

| Qfpm | **Alluvial fans (middle Pleistocene)**—Moderately consolidated, deeply weathered, moderately to poorly sorted sand, silt, and gravel, capped with moderately well drained, maximally developed soils |
| Qtlp | **Fluvial terrace deposits (late Pleistocene)**—Semi-consolidated, moderately to poorly sorted silt, sand, silty clay, and gravel |
| Qtmp | **Fluvial terrace deposits (middle Pleistocene)**—Semi-consolidated, moderately well to poorly sorted sand, silt, and clay with interbedded gravel |
| Qct | **Coastal terraces, undifferentiated (Pleistocene)**—Semiconsolidated, moderately well-sorted marine sand containing thin, discontinuous gravel-rich layers. Locally includes some terrace surfaces and debris flow deposits resting on terrace surfaces |
| QTc | **Continental deposits, undifferentiated (Pleistocene-Pliocene?)**—Semiconsolidated, relatively fine-grained, oxidized sand and silt. Probably equivalent to Paso Robles Formation |
| Tm | **Monterey Formation, siliceous mudstone (Miocene)**—Light brown to white, hard, brittle, platy; Mohnian Stage. Mapped as McLure Shale Member northeast of San Andreas fault |
| Tml | **Monterey Formation, semi-siliceous mudstone (middle Miocene)**—Semi-siliceous mudstone and siltstone (Sandholdt Shale Member of Durham, 1968, 1974) |
| Kgdm | **Porphyritic granodiorite of Monterey (Ross, 1976) (Cretaceous)** |
| ———— | **Contact**—Accuracy ranges from well-located to approximately located. Most sedimentary units are well-located and most igneous and metamorphic units are approximately located at main mapping scale of 1:62,500 |
| ——— — —?—·····?·· | **Fault**—Solid where accurately located; dashed where approximately located; dotted where concealed; queried where location or existence uncertain. Includes strike-slip, normal and reverse dip-slip, oblique-slip, and thrust faults |

EXISTING WASTEWATER FACILITIES — PROJECT COMPONENT

H — **High liquefaction susceptibility**— Engineering tests and shallow ground water, the local presence of free faces, or historical evidence of liquefaction-induced ground failure in the 1906 San Francisco or 1989 Loma Prieta earthquakes. Mainly latest Holocene (0-500 years before present) younger flood-plain deposits and most Holocene basin deposits, undivided alluvial deposits, and abandoned channel-fill deposits. Sediments are likely to liquefy in a nearby major earthquake

M — **Moderate liquefaction susceptibility**—Historical evidence of liquefaction-induced ground failure absent, although high susceptibilities calculated in engineering tests. Includes late Holocene (500-5,000 years before present) older flood-plain deposits, colluvium, and some late Pleistocene-Holocene eolian deposits. May liquefy in a nearby major earthquake

L — **Low liquefaction susceptibility**—Includes almost all Pleistocene deposits and pre-Quaternary deposits, and Holocene deposits where the historical high ground water table is at least 30 feet below the ground surface (e.g., most alluvial fan deposits). Unlike to liquefy, even in a nearby major earthquake

V — **Variable liquefaction susceptibility**—Areas of mapped artificial fill. Depending on the type of material and method of placement, the susceptibility may range from high to low

**Historical liquefaction present in 1906 San Francisco or 1989 Loma Prieta earthquakes**

**Historical liquefaction absent in 1906 San Francisco or 1989 Loma Prieta earthquakes**

# 1. INTRODUCTION

Monterey Regional Water Pollution Control Agency (MRWPCA), in partnership with Monterey Peninsula Water Management District (MPWMD), is developing the Proposed Pure Water Monterey Groundwater Replenishment (GWR) Project (Proposed Project) to provide a high-quality recycled water supply for the northern Monterey County area. The Proposed Project consists of two components: advanced treated water for injection in the Seaside Groundwater Basin to replace urban supplies (the GWR Facilities) and additional recycled water for irrigation supplies to be provided through the existing Castroville Seawater Intrusion Project (CSIP). Specifically, MRWPCA plans to construct and operate an advanced water treatment facility (AWTF) to produce up to 3,700 acre feet per year (AFY) of highly-purified recycled water for conveyance to and recharge in the Seaside Groundwater Basin. In addition, MRWPCA would deliver approximately 4,750 to 5,290 AFY of supplemental water to the CSIP area.

In accordance with the California Environmental Quality Act (CEQA), MRWPCA as the lead agency is preparing an Environmental Impact Report (EIR) for the Proposed Project. This report is being prepared to assess potential impacts of the Proposed Project on groundwater resources. Although the Seaside Basin recharge and CSIP delivery components of the Proposed Project are closely related, this impacts assessment report focuses on groundwater impacts from injection and recovery of the Proposed Project water (product water) in the Seaside Basin. Potential impacts from the irrigation water component are addressed separately in the EIR.

This recharge impacts assessment report provides details on proposed recharge facilities including injection wells (Injection Well Facilities) and general information on how the Proposed Project would be constructed and operated. In addition, an analysis of potential impacts from the Proposed Project on groundwater resources (including water levels and quality) is presented to support the EIR.

## 1.1. GWR FACILITIES

The Proposed Project would provide up to 3,700 AFY of product water for recharge in the Seaside Groundwater Basin (or Seaside Basin). The feed water for treatment at the new AWTF would be secondary-treated municipal wastewater from MRWPCA's Regional Treatment Plant (RTP). Prior to treatment at the RTP, the raw municipal wastewater would be augmented by urban stormwater/runoff, agricultural wash water, and runoff collected in local drainage ditches including the Reclamation Ditch, the Blanco Drain, and Tembladero Slough. The AWTF would include pre-treatment (using pre-screening, ozone, and potentially biologically activated filtration); membrane filtration; reverse osmosis (RO); advanced oxidation (AOP) using ultraviolet light (UV) and hydrogen peroxide; and product water stabilization with calcium and alkalinity.

The AWTF recycled water would be conveyed by pipeline from the AWTF to newly-constructed shallow and deep recharge (injection) wells in the north-central portion of the

Seaside Basin (Figure 1). Recharged water would be stored in the groundwater basin for subsequent extraction by California American Water Company (CalAm) using existing production wells. The Proposed Project would increase the basin yield and allow CalAm to reduce Carmel River diversions in compliance with a state order to secure replacement water supplies (MRWPCA, May 2013).

Recycled water would be recharged into the Seaside Basin's two primary aquifers used for water supply - the Paso Robles Aquifer and the underlying Santa Margarita Aquifer. Recharge would be accomplished through relatively shallow vadose zone wells (Paso Robles Aquifer) and deep injection wells (Santa Margarita Aquifer). Locations of the Proposed Project Injection Well Facilities site and proposed vadose zone and deep injection wells are shown on Figure 2.

This report focuses on the Proposed Project recharge, storage, and recovery operations and analyzes potential impacts from the Proposed Project on groundwater resources. The groundwater impacts assessment will provide technical support for the EIR.

## 1.2. Report Goal and Objectives

The goal of this report is to assist with development and implementation of the Proposed Project by developing and analyzing the recharge components of the project. Specifically, the recharge components include recharge wells (also referred to as injection wells), operational facilities, and the fate and transport of the recycled water in the groundwater basin. To achieve this goal, the following objectives have been identified for this report:

- provide the technical basis for Proposed Project recharge components including wells and operational facilities
- support the EIR with a groundwater impacts analysis
- outline potential steps for construction and operation of the recharge components of the Proposed Project
- provide a preliminary schedule for construction of recharge components
- incorporate existing studies for project development and implementation.

## 1.3. Incorporation of Recent Studies

Numerous studies have been conducted involving various aspects of the Proposed Project. Collectively, these studies provide the technical basis for project development and operations and support ongoing analyses including preparation of an EIR. Studies summarized below are the most relevant for the groundwater and recharge components of the Proposed Project and do not represent a comprehensive list. The following descriptions of the studies provide an understanding of how the work done by others is incorporated into this report.

### 1.3.1. MRWPCA Field Program

In December 2013 and January 2014, Todd Groundwater developed and implemented a field program (referred to herein as the MRWPCA field program or field program) in the vicinity of the Proposed Project Injection Well Facilities site. The field program involved data collection and testing through the 400 feet of vadose zone and installation and sampling of a new monitoring well drilled to a depth of 535 feet. The entire borehole was continuously cored and selected core samples were analyzed for hydraulic properties, mineralogy, and leaching potential. The new well, MRWPCA MW-1, is screened in the upper Paso Robles Aquifer and is capable of monitoring the water table beneath the site. MRWPCA MW-1 and five existing nearby production and monitoring wells were sampled to supplement existing groundwater quality data in the area. MRWPCA MW-1 and the five additional wells (FO-7 Shallow, FO-7 Deep, PRTIW, ASR MW-1, and Seaside 4) are shown on Figure 2.

The field program also included an analysis of potential geochemical changes in groundwater as a result of the Proposed Project. In conformance with the State Recycled Water Policy (California SWRCB, 2013), a Regional Water Quality Control Board may impose restrictions on a proposed groundwater replenishment project if the project changes the geochemistry of an aquifer thereby causing the dissolution of constituents from the geologic formation into groundwater. To assess if the Proposed Project has the potential to cause dissolution, laboratory leaching analyses were conducted on core samples to ensure the protection of groundwater beneath the Proposed Project's vadose zone wells. Results of the leaching analyses were further analyzed using geochemical modeling.

Results of the program have been documented and analyzed in a separate report prepared by Todd Groundwater (Todd Groundwater, 2015). The groundwater quality data collected during the MRWPCA field program, along with the results of the core leaching analyses and associated geochemical modeling, are incorporated herein (see sections 7.3 and 7.4) to assist with the assessment of potential impacts from the Proposed Project on groundwater quality.

### 1.3.2. Proposed Project Product Water Quality

MRWPCA constructed a GWR pilot treatment plant on the RTP site to evaluate treatment options for the AWTF and collected data to characterize the water quality of the product water and reverse osmosis concentrate by-product. The GWR pilot plant product water was analyzed for various constituents as the treatment process was adjusted and optimized. Analyses demonstrated that the product water would meet drinking water standards. However, the GWR pilot plant did not include a process to provide chemical stabilization, which would be included in the proposed AWTF to protect against corrosion in conveyance pipelines and recharge wells. The planned stabilization would also limit the potential for product water injected into the Proposed Project vadose zone wells to leach constituents from the geologic formation and impact groundwater quality as mentioned above. Bench scale chemical stabilization was conducted on the GWR pilot plant product water to simulate final water quality and to allow for evaluation of the leaching potential of the recycled water as part of the laboratory leaching analyses. Additional details and water quality data of the bench scale water sample are provided in Section 7.3.4. Results of the leaching analyses and geochemical modeling are summarized in Section 7.3.5 of this report. Details of the analysis and an expanded discussion of the results are presented in the draft report on the field program (Todd Groundwater, 2015).

### 1.3.3. Groundwater Modeling with the Seaside Basin Watermaster Model

To provide a quantitative assessment of the Proposed Project impacts on water levels and other production wells, and to assess changing conditions relating to the potential for seawater intrusion, a basin-wide numerical model has been used. Specifically, the Seaside Basin Watermaster has constructed and calibrated a multi-layer transient groundwater flow model using MODFLOW 2005. HydroMetrics WRI (HydroMetrics), consultant to the Seaside Basin Watermaster, has been retained by MRWPCA to apply the Watermaster model to simulate potential impacts of the Proposed Project on groundwater resources. Results of the modeling are presented in a technical memorandum (TM), included as Appendix C of this report and summarized herein.

## 2. RECYCLED WATER DELIVERY FOR RECHARGE

MRWPCA has evaluated the amounts and availability of the Proposed Project source waters and has developed estimates of monthly deliveries of recycled water to the Seasisde Basin. On average, about 3,500 AFY would be delivered to the Seaside Basin, but monthly amounts would vary based on hydrologic conditions.

Specifically, the Proposed Project would incorporate the concept of a drought reserve account. During wet and normal years, the Project would convey an extra 200 acre feet (AF) of advanced treated water to the Seaside Basin for recharge and storage, up to a cumulative total of 1,000 acre feet. During dry conditions, the Project could reduce its deliveries to the Seaside Basin by as much water as had accumulated in the drought reserve. The Project water that is not delivered to the Seaside Basin would instead be used to augment irrigation supplies delivered through the CSIP. CalAm would continue to extract 3,500 AFY for municipal supplies by using the water stored in the drought reserve. These operational guidelines have been translated into potential monthly delivery amounts to the Seaside Basin as discussed in more detail below.

### 2.1. DELIVERY SCHEDULES AND OPERATION OF THE DROUGHT RESERVE ACCOUNT

MRWPCA has evaluated the availability and amounts of source waters, capacity of the AWTF, minimum delivery targets, and operational guidelines discussed above in order to develop potential delivery schedules for recharge to the Seaside Basin. Based on this analysis, there are eight potential delivery schedules that could occur, based on two water management decision points made in each year of GWR operation. These eight delivery schedules are presented in Table 1. The two management decisions that determine appropriate deliveries to the Seaside Basin are described below.

The first management decision would be made by October 1, the beginning of the water year,[1] and would dictate which of two delivery schedules is followed during October through March of that water year. The decision would be based on whether or not the drought reserve account is full (1,000 AF). If the account is full, the project would deliver monthly amounts from October through March based on average annual deliveries (highlighted in purple on Table 1; for example, see October through March deliveries for Schedule 2 and Schedule 8). If the account balance is less than 1,000 AF on October 1, then an additional 200 AF would be delivered from October through March (highlighted on Table 1 in blue; for example, see October through March delivery schedules 1, and 3 through 7). For wet or normal years, these two recharge schedules would produce a total of 3,700 AFY (Schedule 1) or a total of 3,500 AFY (Schedule 2) (Table 1).

[1] A Water Year is defined as October 1 through September 30, and is based on the annual precipitation pattern in California. The Water Year is designated by the calendar year in which it ends.

## Table 1. Product Water Available for Injection

| | Product Water Delivery Schedules for Seaside Basin Injection | | Acre-Feet per Month (AF/month) | | | | | | | | | | | | Total | Add to | Available |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | | | Oct | Nov | Dec | Jan | Feb | Mar | Apr | May | June | July | Aug | Sep | AFY | Reserve | in Reserve |
| 1 | Drought Reserve <1,000 AF | Wet/Normal Year | 331 | 321 | 331 | 331 | 299 | 331 | 288 | 297 | 288 | 297 | 297 | 288 | 3,700 | 200 | - |
| 2 | Drought Reserve 1,000 AF | Wet/Normal Year | 297 | 288 | 297 | 297 | 268 | 297 | 288 | 297 | 288 | 297 | 297 | 288 | 3,500 | - | - |
| 3 | Drought Reserve <1,000 AF | Drought Year | 331 | 321 | 331 | 331 | 299 | 331 | 255 | 263 | 255 | 263 | 263 | 255 | 3,500 | 200 | 200 |
| 4 | Drought Reserve <1,000 AF | Drought Year | 331 | 321 | 331 | 331 | 299 | 331 | 222 | 229 | 222 | 229 | 229 | 222 | 3,300 | 200 | 400 |
| 5 | Drought Reserve <1,000 AF | Drought Year | 331 | 321 | 331 | 331 | 299 | 331 | 189 | 196 | 189 | 196 | 196 | 189 | 3,100 | 200 | 600 |
| 6 | Drought Reserve <1,000 AF | Drought Year | 331 | 321 | 331 | 331 | 299 | 331 | 156 | 162 | 156 | 162 | 162 | 156 | 2,900 | 200 | 800 |
| 7 | Drought Reserve <1,000 AF | Drought Year | 331 | 321 | 331 | 331 | 299 | 331 | 124 | 128 | 124 | 128 | 128 | 124 | 2,700 | 200 | 1,000 |
| 8 | Drought Reserve 1,000 AF | Drought Year | 297 | 288 | 297 | 297 | 268 | 297 | 124 | 128 | 124 | 128 | 128 | 124 | 2,500 | - | 1,000 |

| Maximum Monthly Injection Rates | Injection Rates in Gallons per Minute (gpm) | | | | | | | | | | | | Maximum |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | Oct | Nov | Dec | Jan | Feb | Mar | Apr | May | June | July | Aug | Sep | (gpm) |
| Santa Margarita Aquifer (90%) | 2,175 | 2,179 | 2,175 | 2,175 | 2,175 | 2,175 | 1,955 | 1,951 | 1,955 | 1,951 | 1,951 | 1,955 | 2,179 |
| Paso Robles Aquifer (10%) | 242 | 242 | 242 | 242 | 242 | 242 | 217 | 217 | 217 | 217 | 217 | 217 | 242 |
| Total | 2,417 | 2,422 | 2,417 | 2,417 | 2,417 | 2,417 | 2,173 | 2,168 | 2,173 | 2,168 | 2,168 | 2,173 | 2,422 |

The second management decision would be made in early Spring as to which schedule will be followed for deliveries in April through September. This decision would be based on whether or not the previous 6 months of precipitation has indicated a drought year and whether supplemental irrigation water is needed and available from the drought reserve account. This decision would be made by the Monterey County Water Resources Agency (MCWRA). If it is a wet/normal year, the delivery would follow the April through September delivery schedule shown for both Schedule 1 and Schedule 2. However, if MCWRA requests water from the drought reserve account during a drought year, the delivery schedule for April through September would follow one of the drought delivery schedules shown in green on Table 1. The selection of the drought schedule would be based on the then-current balance in the drought reserve account (as of April 1 – see last column on Table 1).

## 2.2. MAXIMUM DELIVERY FOR RECHARGE

The maximum monthly amount of advanced-treated recycled water available from any of the eight potential delivery schedules on Table 1 has been converted to a maximum monthly injection rate in gallons per minute (gpm) for each aquifer. These rates are summarized in the lower portion of Table 1. The maximum injection rates are estimated for planning purposes to design recharge facilities that will accommodate peak flows and to inform the number and spacing of injection wells. As shown in Table 1, the total maximum injection rate for any of the schedules is 2,422 gpm (lower right on Table 1). Assuming 90 percent of the water is injected into the deeper Santa Margarita Aquifer, deep injection wells need to accommodate an estimated peak flow of about 2,179 gpm (see Section 3.3.5.1 for an explanation on allocating recharge between the two aquifers). Assuming 10 percent of the water is injected into the Paso Robles Aquifer, shallow injection (or vadose zone) wells would need to be capable of injection rates up to about 242 gpm.

For the purposes of project planning and EIR analysis, recharge facilities are sized for these maximum rates incorporating conservative injection rates and allowing for down-time associated with well operation and maintenance. As actual operation is refined, monthly injection amounts can be balanced with operation at the AWTF, as needed. However, this approach provides future project flexibility and allows for evaluation of reasonable "worst-case" potential environmental impacts on groundwater resources associated with the recharge component of the Proposed Project.

# 3. PROJECT LOCATION AND HYDROGEOLOGIC SETTING

## 3.1. GROUNDWATER BASIN AND STUDY AREA

The Proposed Project Injection Well Facilities site is located within a portion of the Seaside Subbasin of the Salinas Valley Groundwater Basin as defined by the California Department of Water Resources (CDWR) in the Bulletin 118 description of California's groundwater basins (CDWR, 2004). The boundaries of the Seaside Subbasin and delineation of four subareas within the subbasin have been redefined by Yates et al. (2005) based on a reinterpretation of geologic faulting and groundwater flow divides. The northern basin boundary is based on a groundwater divide that is subject to movement with changing conditions in groundwater levels (Yates, et al., 2005; HydroMetrics, 2010).

The redefined subbasin covers about 20 square miles and is referred to as the Seaside Groundwater Basin, or simply Seaside Basin, in this report. The boundaries of the Seaside Groundwater Basin and four subareas are shown on Figure 1. Basin wells (including production and monitoring wells) are also shown on the figure to highlight areas of groundwater development. Figure 2 includes production and monitoring wells in the vicinity of the Proposed Project Injection Well Facilities.

The Proposed Project Injection Well Facilities would be located within the northeastern-most subarea of the Seaside Groundwater Basin, referred to as the Northern Inland Subarea (Figure 1). The site is close to the Northern Coastal Subarea where most of the basin's groundwater pumping occurs (as indicated by the relatively large number of wells on Figure 1). Groundwater production also occurs in the Southern Coastal Subarea and the Laguna Seca Subarea.

Historically, only minimal pumping has occurred within the Northern Inland Subarea. Of the three wells in the subarea shown on Figure 1, only one well - the City of Seaside Reservoir Well (identified on Figure 2) - has provided water supply. The other two wells in the Northern Inland Subarea are monitoring wells. The subarea has remained largely undeveloped as a result of its long-term use as a large firing range by the U.S. Army on the former Fort Ord military base, which closed in 1994.

The southern subareas are considered less hydraulically connected to the Proposed Project Injection Well Facilities area and are not included in the Study Area for the impact analysis. Accordingly, for the purposes of the impact analysis, the Study Area is defined as the Northern Inland and Northern Coastal subareas of the Seaside Groundwater Basin.

### 3.1.1. Seaside Basin Adjudication

The Seaside Basin was adjudicated by the California Superior Court on March 27, 2006, establishing groundwater extraction rights in the basin. A court-appointed Watermaster has been formed to execute the requirements of the adjudication. The court decision requires a decrease in pumping after three years from the effective date of the adjudication (and additional pumping reductions over time) unless the Watermaster has secured additional sources of water from outside the basin for injection into the basin or for replacing pumping (i.e., in lieu replenishment). Further, the Watermaster has responsibilities with respect to securing replenishment water from outside the basin to offset the over-production in the basin.

### 3.1.2. Groundwater Use

Groundwater pumping in the Seaside Groundwater Basin provides water supply for municipal, irrigation (primarily golf courses), and industrial uses. Historically, about 70 to 80 percent of the pumping has occurred in the Northern Coastal Subarea, with additional pumping occurring in the Laguna Seca Subarea supplemented by small amounts in the Southern Coastal Subarea. CalAm is the largest pumper in the basin accounting for about 79 percent of the groundwater pumped in water year (WY) 2013[2] (Watermaster, 2013).

Available annual pumping in the Coastal subareas and total basin production over the last 20 years are shown on Figure 3. Over this time period, production in the Coastal subareas has averaged about 4,000 AFY and total basin production has averaged about 5,000 AFY.

Prior to basin adjudication in 2006, pumping exceeded sustainable yield and contributed to significant basin-wide water level declines. Over-pumping in the coastal subareas resulted in water levels declining below sea level at the coast, placing aquifers at risk of seawater intrusion. In particular, basin pumping increased after a 1995 order by the State Water Resources Control Board (SWRCB) placed constraints on out-of-basin supplies (Figure 3).

Since 2008, groundwater pumping has declined. Pumping in coastal subareas averaged about 4,505 AFY from 1996 through 2008, but has decreased to about 3,288 AFY from 2009 through 2013 (Watermaster production records). For comparison purposes, the court established a natural safe yield for the coastal subareas of between 1,973 AFY to 2,305 AFY during the Seaside Basin adjudication (California Superior Court, 2006).

The production data in Figure 3 do not include injection and recovery from the nearby Monterey Peninsula Aquifer Storage and Recovery Project (ASR Project) where about 1,100 AFY has been injected and/or recovered from 2010 through 2012. Details of that project are summarized in the following subsection.

### 3.1.3. ASR Project

The ASR Project is operating in the Seaside Basin downgradient and within about 1,000 feet from the Proposed Project Injection Well Facilities site. CalAm and MPWMD are in partnership in implementing the ASR Project, which involves the injection of treated Carmel River Basin groundwater into a series of ASR wells for seasonal storage in the basin and subsequent recovery for drinking water supply.

---

[2] Water Year (WY) 2013 begins October 1, 2012 and ends September 30, 2013.

Currently, Carmel River Basin water (extracted from riverbank wells) is treated to drinking water standards and conveyed to the ASR wells for recharge when excess water is available (e.g., periods when flows in the Carmel River exceed fisheries bypass flow requirements). The ASR wells are also planned for injection of product water from a proposed ocean desalination plant to be developed by CalAm.

As of 2014, four ASR wells have been installed along General Jim Moore Boulevard in the City of Seaside, California (Figure 2). ASR-1 and ASR-2 are located about 1,000 feet northwest of the Proposed Project Injection Well Facilities site. ASR-3 and ASR-4 are located about 1,600 feet to the northwest of the Proposed Project wells (Figure 2).

The amount of Carmel River water injected varies from year to year depending on availability; specifically, diversions from the Carmel River for ASR injection are limited to certain times of the year and are allowed only when minimum flows are present at certain gages on the Carmel River (i.e., to provide adequate fish passage). Table 2 summarizes river water that has been injected and recovered as part of the ASR Project for the last five complete water years.

**Table 2. Injection and Recovery Volumes, ASR Project**

| Water Year | ASR Injection (AFY) | ASR Recovery (AFY) |
|---|---|---|
| 2010 | 1,110 | 0 |
| 2011 | 1,117 | 1,110 |
| 2012 | 131 | 1,117 |
| 2013 | 294 | 644 |
| 2014 | 0 | 0 |
| Total | 2,652 | 2,871 |

Although data in Table 2 indicate that the ASR Project has recovered more water than injected over the last four years, the table does not include the full historical record of all of the injected water as the first ASR test well was drilled in 1998. A regulatory order requires that the injected Carmel River water be extracted to meet demands, and the project is not operated for the long-term replenishment of basin aquifers (i.e., recharge that is kept in the basin without extraction) (Watermaster, 2012).

### 3.1.4. Watermaster Numerical Model

In 2009, the Seaside Basin Watermaster completed construction of a numerical groundwater flow computer model for the basin using the model code MODFLOW 2005 (HydroMetrics, 2009). The model provides a basin-wide tool for evaluating protective water levels and various groundwater management strategies.

The Watermaster model covers approximately 76 square miles of the Salinas Valley Groundwater Basin including the Seaside Groundwater Basin. In order to represent the hydrostratigraphy and simulate three-dimensional flow in the basin, the model was constructed with five layers. Model layers generally correspond to observed hydrostratigraphic units[3] as follows:

- Layer 1 - Older Dune deposits and Aromas Red Sand
- Layers 2 and 3 - Upper and Middle Paso Robles Aquifer
- Layer 4 - Basal clay layers (approximately 80 feet thick) typically observed in the Lower Paso Robles Formation, where present
- Layer 5 - Santa Margarita Aquifer (including the Purisima Formation where present).

Additional details on the basin hydrostratigraphy and aquifers are discussed in Section 4 of this report.

The Watermaster model is a transient model that has been calibrated over a 22-year period from January 1987 through December 2008 and is capable of simulating groundwater levels over a wide variety of hydrologic conditions. The model includes conditions that occur during the drought period of the early 1990s and relatively wet periods such as 1998 and 2005. Boundary conditions and additional details on the Watermaster model are documented in a report on model construction and calibration (HydroMetrics, 2009).

The model provides a valuable quantitative tool for the evaluation of the Proposed Project and potential impacts to basin water levels and wells. HydroMetrics has been contracted by MRWPCA to apply the model to simulate aquifer response to various conditions including No-Project conditions and conditions associated with the Proposed Project. Modeling results are provided in the appendices and summarized in the impacts section of this report (Section 7).

## 3.2. PROPOSED PROJECT INJECTION WELL FACILITIES SITE

The Proposed Project Injection Well Facilities would be located along a strip of land on the eastern boundary of the City of Seaside, California and about 1.5 miles inland from Monterey Bay (Figure 1). Facilities would be constructed within an approximate 150-feet wide corridor of land about 3,000 feet long (Figure 2). The corridor would begin approximately 1,200 feet south of Eucalyptus Road, and would extend south-southwest for approximately 3,000 feet toward General Jim Moore Boulevard. The southwestern end of the Injection Well Facilities site would be approximately 200 feet east of General Jim Moore Boulevard.

The Proposed Project Injection Well Facilities would be situated along existing unimproved roads of former Fort Ord lands and along the edge of two parcels that are proposed for

---

[3] A hydrostratigraphic unit can be defined as a formation, part of a formation, or groups of formations in which there are similar hydraulic characteristics allowing for grouping into aquifers or confining layers (aquitards).

conveyance from the Fort Ord Reuse Authority to the City of Seaside. This property boundary has been identified by the City of Seaside as functioning as a utility right-of-way corridor where the Proposed Project wells could be located for minimum interference with future land use plans. The site was selected using the following criteria:

- upgradient of existing CalAm production wells for efficient recovery of recharged project water that has comingled with native groundwater and ASR-injected Carmel River water
- within areas of favorable aquifer properties for replenishment and groundwater production, such as relatively high transmissivity and sufficient aquifer thickness
- sufficiently deep water table to provide a large local storage volume
- close to pumping depressions[4] to provide replenishment water to areas of declining water levels.

Over the last few years, several alternate proposed project Injection Well Facilities locations within the Seaside Basin were considered for project development. Two locations, previously referred to as the Coastal location and the Inland location, were considered favorable and were evaluated in 2009 during early project development. Since that time, further analyses have been conducted and the Coastal location has been eliminated from consideration due to hydrogeologic conditions, engineering factors, and costs. A discussion of the selection of the current Proposed Project Injection Well Facilities location as the preferred location over the Coastal location is documented in a TM provided in Appendix A (Todd Groundwater, May 2014). The current Proposed Project site Injection Well Facilities has been modified slightly from the previously considered inland location to optimize project performance.

### 3.2.1. Physical Setting

The Proposed Project Injection Well Facilities are located on an upper coastal plain of low hills and mature dunes that slopes northward toward the Salinas Valley and westward toward Monterey Bay (approximately 1.5 miles to the west) (Figure 1). The Proposed Project Injection Well Facilities area is characterized by rolling hills and closed depressions. The area is currently undeveloped and surrounded by natural vegetation that is cross-cut by unimproved roads and trails associated with former military activities (Figure 2). An access road to a small water reservoir is across Eucalyptus Road from the northern-portion of the Proposed Project Injection Well Facilities area. This reservoir and adjacent groundwater well have been used historically for irrigation at a golf course west of General Jim Moore Boulevard (Figure 2).

### 3.2.2. Topography

The ground surface elevation rises across the groundwater basin from sea level at the coast to more than 800 feet above mean sea level (msl) in the southeastern portions of the basin.

[4] As groundwater is pumped, water levels are lowered in the aquifer creating a zone of water levels lower than ambient levels, and referred to as a cone of depression around the pumping well(s).

For the area shown on Figure 2, ground surface elevations rise to about 550 feet msl in the east central portion of the map. Along Eucalyptus Road, ground surface elevations vary from about 470 feet msl at the monitoring well identified as FO-7 to about 430 feet msl at the recently drilled monitoring well identified as MRWPCA MW-1, down to about 340 feet msl at General Jim Moore Boulevard and at ASR-1 (Figure 2). Ground surface elevations along the Proposed Project area vary from about 455 feet msl at proposed DIW-1, 396 feet msl at DIW-2, sloping downward to about 300 feet msl at DIW-4.

### 3.2.3. Climate and Hydrology

The Proposed Project Injection Well Facilities area receives about 14.5 inches of annual rainfall (Yates, et al., 2005). Runoff on the rolling hills collects in low areas and provides recharge to the Seaside Groundwater Basin. Recharge from deep percolation of rainfall (and minor amounts of irrigation) in the Northern Inland Subarea has averaged about 1,080 AFY from 2003 through 2007 (HydroMetrics, 2009). This amount represents 99 percent of the total recharge estimated for this undeveloped subarea (HydroMetrics, 2009). (Additional sources of recharge allow for the natural safe yield from adjacent coastal subareas to be higher as noted in Section 3.1.2).

### 3.2.4. Land Use

The Proposed Project Injection Well Facilities would be located on a portion of the former Fort Ord military base, which provided training and staging for U.S. troops from 1917 to 1994. The proposed site is on the northwestern edge of a large upland area referred to as the Inland Ranges (HLA, 1994). The Inland Ranges consist of about 8,000 acres bounded by Eucalyptus Road to the north, Barloy Canyon Road to the east, South Boundary Road to the south, and General Jim Moore Boulevard to the west. For environmental investigation and remediation purposes on former Fort Ord lands, a portion of the area is also referred to as Site 39. The general area of the Inland Ranges and the area of the Proposed Project wells are shown on Figure 4.

Site 39 contained at least 28 firing ranges that were used for small arms and high explosive ordnance training using rockets, artillery, mortars and grenades. Range 18 (HA-18) and Range 19 (HA-19) are the closest ranges to the Proposed Project Injection Well Facilities location (approximately 200 feet south and east), with Range 48 (HA-48) farther east (Figure 4).

Considerable expended and unexploded ordnance (UXO) have been documented in various areas of Site 39. The specific ordnance types include rounds from shotguns, mortars, M74 rockets, recoilless rifles, aircraft, grenades, artillery, howitzers, mines, anti-tank weapons (bazookas), bombs, naval ordnance, Bangalore torpedoes, C-4, TNT, military dynamite, and shaped charges. Functions for these items included high explosives, heat generating, armor piercing, white phosphorous, smoke tracer, illumination, incendiary, and photo flash devices. As a result of the spontaneous ignition of a white phosphorous grenade in August 2009, a Munitions and Explosives of Concern (MEC) sweep was conducted at Range 48. This surface sweep removed MEC or MEC-like items using physical and demolition methods.

Beginning in 1984, numerous environmental investigation and remediation activities have occurred on Site 39. During these investigations, metals and various compounds associated with explosives have been detected in soil. Remediation has been more extensive in areas targeted for redevelopment, an area that includes the Proposed Project Injection Well Facilities site.

Most of these lands are now controlled by the Fort Ord Reuse Authority (FORA), the organization responsible for the planning, financing, and implementing the conversion of former Fort Ord military lands to civilian activities. FORA has signed an Environmental Services Cooperative Agreement (ESCA) with the U. S. Army to allow transfer of approximately nine parcels (3,340 acres) that were associated with military munitions (e.g., unexploded ordnance (UXO) or munitions and explosives of concern (MEC)). Under ESCA, FORA is responsible for addressing munitions response actions. FORA and their contractors are working with regulatory agencies including the California Department of Toxic Substances Control (DTSC) and the U.S. Environmental Protection Agency (USEPA) to conduct munitions remediation activities, scheduled for completion by 2015.

Most of the ESCA parcels, including the area of the Proposed Project wells, will ultimately be transferred to the City of Seaside. The ESCA parcels that contain the Proposed Project Injection Well Facilities were less impacted by former Fort Ord activities than other parcels associated with Site 39 and have already been cleared of MEC and approved for future development. The Proposed Project wells are purposefully located along the southern-southeastern edge of the parcels and are not expected to interfere with future re-development by the City of Seaside (Figure 4). By spacing the wells along the parcel boundary, it is anticipated that any visual or noise concerns would also be minimized in comparison to a configuration where multiple deep injection wells were operating closer together.

## 3.3. Hydrostratigraphy and Target Aquifers

The Seaside Groundwater Basin consists of semi-consolidated to consolidated sedimentary units overlying relatively low permeability rocks of the Miocene Monterey Formation and older crystalline rocks. The sedimentary units consist of deep marine sandstones of Tertiary age overlain by a complex Quaternary-age sequence of continental deposits and shallow Quaternary-age dune deposits. In general, the sedimentary units dip northward and thicken into the Salinas Valley.

The basin has been structurally deformed by geologic folding and faulting. In particular, sedimentary units in the southern portion of the basin have been uplifted and displaced along the Ord Terrace and Seaside faults, which create some hydraulic separation, referred to as compartmentalization, within the basin. Both faults are generally south of the Proposed Project Injection Well Facilities. However, one interpretation of the Ord Terrace fault trace (Yates, et al., 2005) indicates that the fault trends relatively close (within 1,000 feet) to the southern Proposed Project wells (DIW-4 and VZW-4) and could potentially result in some hydraulic separation between the project wells and the closest municipal well to the southwest, Seaside No. 4 (Figure 2). This uncertainty would not affect the Proposed Project operations. As a conservative assumption, the hydrogeologic investigation assumes that the wells are hydraulically connected.

Two main sedimentary units provide the source of groundwater supply for existing pumping operations in the Seaside Basin: the continental Quaternary-age (Pleistocene) Paso Robles Formation and the Tertiary-age (Miocene) Santa Margarita Sandstone. Permeable units in these two geologic formations are referred to herein as the Paso Robles and the Santa Margarita aquifers. Although the Santa Margarita Aquifer is more homogeneous than the Paso Robles Aquifer, both are defined by a series of stratified layers rather than a single continuous sand unit.

The two aquifers are overlain by Quaternary-age units including undifferentiated sediments, eolian sand deposits, and the consolidated Aromas Formation (CDWR, February 2004; Yates et al., 2005). Although these shallow units are highly permeable in most areas, the deposits occur generally above the water table and are only saturated in coastal areas. As such, these shallow units do not contribute substantially to the basin's water supply.

Aquifer parameters and groundwater conditions associated with each of the two target aquifers in the Proposed Project Injection Well Facilities area are discussed in more detail below. Also included is a discussion of vadose zone properties of the older dune sands and Aromas Sand beneath the proposed site to assist in design of recharge wells (vadose zone wells) for the Proposed Project. A geologic cross section, shown on Figure 5, illustrates the subsurface conditions beneath the area. The location of the cross section and corresponding wells are shown on Figure 2. Subsurface conditions and aquifer parameters in the Proposed Project Injection Well Facilities area are also summarized on Table 3 and discussed in the following sections.

## Table 3. Estimated Subsurface Conditions in Proposed Project Area

| | Aromas Sand / Older Dune Deposits | Paso Robles Aquifer | Santa Margarita Aquifer | Data Sources |
|---|---|---|---|---|
| **Lithology** | Fine brown sand, silty sand, some medium to coarse sand, minor silt and clay. | Heterogeneous package of interbeds of sand, silt, and clay mixtures. Average bed thickness of | Fine- to medium-grained well sorted sand to silty sand; sandy silt in lower portions of formation; minor | 1, 2, 3 |
| **Interval Thickness** | 400 feet | 250 feet | 280 feet | 1, 2 |
| **Percent Sand** | 92% | 52% | 74% | 2 |
| **Depth** | Surface sediments | 356 feet | 609 feet | Figure 5; Ground surface elev. |
| **Groundwater Conditions** | unsaturated | unconfined | semi-confined | 4, 5 |
| **Aquifer Parameters** | | | | |
| ***Transmissivity (T)*** | Not applicable; unsaturated locally | 659 feet$^2$/day to 1,524 feet$^2$/day | 11,377 to 13,947 feet$^2$/day<br>24,003 feet$^2$/day | 1, 5, 6, 7, 8, 9 |
| ***Horiz. Hydraulic Conductivity ($K_h$)*** | 350 feet/day | 20 feet/day | 63 feet/day | 2, 6 |
| ***Vertical Hydraulic Conductivity ($K_v$)*** | 70 feet/day | 0.66 feet/day to 16 feet/day | 0.63 feet/day | 1, 3, 7 |
| ***Storativity (S)*** | 0.24 to 0.40 (sand);<br>0.04 to 0.09 (silt; silty sand) | 0.12 | 0.0018<br>0.00258 | 1, 4, 5 |
| **Average Coastal Subarea Production** | Not applicable; unsaturated locally | Est. 500 AFY<br>(15% of total coastal production) | Est. 2,500 AFY<br>(85% of total coastal production) | 9, 10 |
| **Area Water Levels Below Sea Level** | Not applicable; unsaturated locally | 900 acres | >2,000 acres | 9 |

### 3.3.1. Older Dune Sands/Aromas Sand

The shallowest geologic deposits at the Proposed Project Injection Well Facilities site are composed of recent and older eolian sands and older continental deposits of Pleistocene age referred to herein as the Older Dune Sands/ Aromas Sand or Aromas Sand. The unit has been described as also including fluvial and coastal terrace deposits, as well as flood-plain and other basin deposits (Yates, et al., 2005; HydroMetrics, 2009).

The entire sequence was recently cored in a boring for a recently-installed monitoring well by Todd Groundwater in the Proposed Project Injection Well Facilities area (see MRWPCA MW-1 on Figure 2). The unit was described on a geologic log and selected core samples were analyzed at various laboratories to evaluate lithology and mineralogy, porosity and permeability, infiltration rates, leaching potential, and other factors to support the Proposed Project development. Complete laboratory results are documented and analyzed in a separate report (Todd Groundwater, February 2015).

Geologic core descriptions from MRWPCA MW-1 indicate that the Aromas Sand is approximately 400 feet thick in the Proposed Project Injection Well Facilities area and is composed primarily of fine-grain sand (about 92 percent sand) with minor amounts of silt and clay. The upper 300 feet is the most homogeneous with generally higher permeability values. As previously shown on Table 3, the unit is associated with high horizontal hydraulic conductivity (350 feet per day) and vertical hydraulic conductivity (70 feet per day) as estimated from laboratory core data.

The geologic unit is illustrated on the cross section on Figure 5 and ranges from about 225 feet at ASR-1 up to about 400 feet thick at MRWPCA MW-1 and monitoring well FO-7. Also shown on the cross section are geophysical logs for the three existing wells that provide readings of electrical (resistivity) measurements throughout the borehole. Although the logs are provided for illustrative purposes only (without ohm-meter or other electrical scales), log curves show relatively high readings in the Aromas Sand (shaded in orange) [5], generally indicative of higher permeability sediments. The Aromas Sand is unsaturated in the Proposed Project Injection Well Facilities area as indicated by the deeper water levels shown on the cross section (water table and potentiometric surface, Figure 5).

Also projected onto the cross section are schematic diagrams of Proposed Project wells (Figure 5). In particular, vadose zone wells (labeled VZW-1 and shown on Figure 2) would be used for recharge into the shallow aquifer. The advanced treated water recharged through vadose zone wells would be released into the Aromas Sand for percolation to the water table. Selection of vadose zone wells as a recharge method is discussed in subsequent sections of this report. Details of the Proposed Project wells, including preliminary designs, are provided in Section 4.

---

[5] Logs were unavailable in the upper portions of ASR-1 and FO-7 due to shallow surface casings. Log in MRWPCA MW-1 is a cased-hole induction log.

### 3.3.2. Paso Robles Aquifer

Beneath the Aromas Sand is the Paso Robles Formation (Figure 5). The formation is heterogeneous and contains interbeds of sand, silt, and clay mixtures (Yates et al., 2005). Silt and clay layers are described by a variety of colors including yellow-brown, reddish brown, whitish gray, and dark bluish gray, indicating a variety of depositional and geochemical environments. These continentally-derived deposits are discontinuous and difficult to correlate from well to well in the basin.

The formation is saturated in the Proposed Project Injection Well Facilities area (and coastal areas) and forms the shallow aquifer in the basin (referred to as the Paso Robles Aquifer herein). Permeable units in the Paso Robles aquifer are screened in several production wells downgradient of the Proposed Project Injection Well Facilities area.

The heterogeneous nature of the aquifer can be seen on the electric logs from FO-7, ASR-1, and MRWPCA MW-1 in the Proposed Project Injection Well Facilities area (Figure 5). As shown from the logs, resistivity readings (right of the depth columns) are highly variable throughout the Paso Robles Aquifer, indicating interbeds of varying thicknesses. The upper 50 to 100 feet of the aquifer appear to contain a higher percentage of sand, indicating relatively higher permeability. These sands are screened in MRWPCA MW-1. Below the upper sand unit, the formation becomes more heterogeneous and generally more fine-grained. A lower, more permeable layer in the Paso Robles aquifer is screened in FO-7 at about 600 feet deep (about -125 feet msl). Using an approximate sand indicator of 25 ohm-meters on the electric log of a nearby Paso Robles test well, the overall Paso Robles aquifer is estimated to contain about 52 percent sand (Table 3).

#### 3.3.2.1. Paso Robles Aquifer Parameters

The ability of an aquifer to transmit, store, and yield reasonable quantities of water is reflected in aquifer parameters including transmissivity (T), horizontal hydraulic conductivity (K or $K_h$), and storativity (S). These parameters for the Paso Robles Aquifer have been compiled and reviewed by previous investigators in the basin (Fugro, 1997; Yates et al., 2005; HydroMetrics, 2009). In the Proposed Project Injection Well Facilities area, representative aquifer parameters include a T value of about 659 square feet per day ($ft^2$/day) to 1,524 $ft^2$/day, a K value of 20 ft/day and an S value of 0.12 (dimensionless), reflecting an effective porosity of 12 percent. These parameters for the Paso Robles Aquifer are listed in Table 3.

#### 3.3.2.2. Groundwater Recharge in the Paso Robles Aquifer

The Paso Robles aquifer is recharged mainly from surface infiltration of precipitation (HydroMetrics, 2009). The formation crops out in the eastern portion of the basin where rainfall infiltrates directly into the aquifer units (Yates, et al., 2005). In the Proposed Project Injection Well Facilities area, recharge occurs by percolation through the surficial deposits of the Aromas Sand.

#### 3.3.2.3. Groundwater Production in the Paso Robles Aquifer

The Paso Robles Aquifer is less productive than the deeper Santa Margarita Aquifer, but is screened in several production and monitoring wells near the Proposed Project Injection Well Facilities area. In particular, the Paso Robles is screened in production wells Paralta, Ord Grove, PRTIW, MMP, and Seaside 4, all located within about 1,000 feet west of General Jim Moore Boulevard. In addition, the Reservoir well, located east of General Jim Moore Boulevard and north of Eucalyptus Road, is also screened in the Paso Robles Aquifer. The Paralta and Ord Grove wells are also screened in the deeper aquifer.

Because many wells are screened in both the Paso Robles Aquifer and the Santa Margarita Aquifer, the contribution of the Paso Robles Aquifer to basin production is not known with certainty. Estimates by previous investigators (Yates et al., 2005) indicate that an average of about 40 percent of the coastal area production was from the Paso Robles Aquifer in 2000 through 2003. However, with additional wells in the Santa Margarita Aquifer and changes in production over time, the current contribution from the Paso Robles Aquifer is estimated to be less. Recent analysis indicated that only about 20 percent of the basin pumping was from the Paso Robles Aquifer (HydroMetrics, October 2013 – see Appendix B).

It is expected that this declining trend in Paso Robles Aquifer production will continue into the future as the main producer in the Coastal Subareas, CalAm, transitions from their older wells that were primarily Paso Robles Aquifer wells, to the newer (and higher capacity) wells (i.e., Ord Grove, Paralta, ASR wells), which are primarily Santa Margarita Aquifer wells. Accordingly, the planned 10% allocation of GWR recharge to the Paso Robles Aquifer is reasonable as a future approximation, as further described in subsequent sections of this report (i.e., Section 3.3.5).

### 3.3.3. Santa Margarita Aquifer

The Santa Margarita Sandstone of Pliocene/Miocene age underlies the Paso Robles Aquifer throughout most of the Seaside Basin. The aquifer consists of a poorly-consolidated marine sandstone approximately 250 feet thick in the Northern Coastal subarea of the basin. The unit has apparently been eroded near the southern basin boundary due to uplift from folding and faulting along the Seaside and Chupines faults (Yates et al., 2005).

The Miocene/Pliocene Purisima Formation overlies the Santa Margarita Sandstone in some areas. This unit has been described in more detail along the coast and has been grouped with the Santa Margarita Aquifer in Layer 5 of the basin groundwater model (HydroMetrics, 2009). The Purisima Formation is difficult to delineate using subsurface data and is either thin or not present beneath the Proposed Project Injection Well Facilities area.

The Santa Margarita Aquifer is shown on the cross section on Figure 5. The more homogeneous nature of the Santa Margarita aquifer is illustrated on the geophysical logs for ASR-1 and FO-7. The aquifer is approximately 280 feet thick in the Proposed Project Injection Well Facilities area and contains about 74 percent sand (with the remainder containing sandy silt and minor clay). The aquifer is about 600 feet deep in the Proposed Project Injection Well Facilities area as indicated on Figure 5.

#### 3.3.3.1. Santa Margarita Aquifer Parameters

A review of Santa Margarita Aquifer parameters in the Proposed Project Injection Well Facilities and coastal areas indicated an average T value of 11,377 $ft^2$/day (Fugro, 1997; Padre, 2002). More recent aquifer tests in ASR-1 indicated a similar, but slightly higher, T value of 13,947 $ft^2$/day (Padre, 2002). The Watermaster model has a T value of about 24,000 $ft^2$/day in the Proposed Project Injection Well Facilities area.

Storativity (S) values have been estimated at 0.0018 and 0.00258 (dimensionless) for the Santa Margarita aquifer, indicating semi-confined to confined conditions. The confined nature of the aquifer suggests that groundwater replenishment can raise water levels more quickly and to higher levels than an equivalent amount of recharge in an unconfined aquifer. Parameters for the Santa Margarita Aquifer are summarized in Table 3.

#### 3.3.3.2. Santa Margarita Aquifer Recharge

Most of the recharge to the Santa Margarita Aquifer is assumed to occur by leakage from the overlying Paso Robles Formation, especially in areas where the lower Paso Robles is relatively permeable (Yates, et al., 2005; HydroMetrics, 2009). Recharge also enters the Santa Margarita Aquifer from subsurface inflow from other subareas and north of the basin boundary. Although the Santa Margarita crops out east of the Seaside Groundwater Basin, recharge occurring in the outcrop area has been interpreted to flow with groundwater toward the Salinas Valley away from the Seaside Groundwater Basin.

#### 3.3.3.3. Santa Margarita Aquifer Production

Coastal pumping in the Santa Margarita Aquifer was estimated to average about 2,500 AFY from 1999-2003, or about 60 percent of the coastal subarea production. Recent changes in wells and production intervals indicate that this percentage has increased. Basin-wide, the total production from the Santa Margarita is estimated to be about 80 percent (HydroMetrics, 2013, see Appendix B).

### 3.3.4. Groundwater Occurrence and Flow

As discussed above, groundwater occurs under unconfined and confined conditions in the Seaside Basin. Prior to groundwater development, groundwater flow patterns were generally from inland areas toward the coast. Currently, groundwater flow patterns are controlled by local groundwater pumping and subarea pumping depressions. In addition, groundwater flow patterns are altered near certain subarea boundaries where geologic faulting and other discontinuities have compartmentalized groundwater. In particular, the boundary between northern and southern subareas appears to impede groundwater flow. As pumping has lowered water levels in the northern subareas, changes in water levels and flow patterns across the boundary to the south have become more pronounced, with water levels in the southern subarea remaining higher and less influenced by pumping gradients.

In the Proposed Project Injection Well Facilities area, the unconfined water table occurs in the Paso Robles Aquifer leaving the overlying Aromas Sand unsaturated (Figure 5). To be specific, the water table occurs at a depth of about 400 feet below ground surface (bgs). Groundwater within the Santa Margarita Aquifer is semi-confined by low permeability units in the basal sediments of the Paso Robles Aquifer. Although some leakage occurs, water levels are different in the two aquifers. Differences are less near wells that are pumping from both aquifers. Beneath the Proposed Project Injection Well Facilities area, the potentiometric surface[6] in the Santa Margarita Aquifer is generally about 5 to 10 feet lower than the water table (Figure 5).

Water levels have been monitored in the Seaside Basin for at least 25 years. These data document the decline of water levels in the mid-1990s and a recent partial recovery of water levels in some areas. In general, changes in water levels have occurred in response to changes in groundwater production and ASR operation.

Figure 6 shows a long-term hydrograph of a well in the Northern Coastal Subarea, the PCA East well, to illustrate water level trends and fluctuations since 1989 in coastal areas of the basin. The curve highlighted in orange on Figure 6 represents water levels in the Paso Robles Aquifer and the lower curve represents water levels in the Santa Margarita Aquifer. Figure 7 shows hydrographs in two monitoring wells close to the Proposed Project Injection Well Facilities area, FO-7 and Paralta Test Well (located adjacent to the Paralta production well). Note that data for these wells are displayed from 1994 to 2013, a shorter time interval than shown for the PCA East Well on Figure 6. Similar to the PCA East well, FO-7 also consists of two monitoring points: a shallow well screened in the Paso Robles Aquifer, and a deep well screened in the Santa Margarita Aquifer. The Paralta Test well is screened in both aquifers and represents average water levels, although most of the water appears to be coming from the Santa Margarita Aquifer. Locations of the wells with hydrographs on Figures 6 and 7 are shown on Figure 8.

Hydrographs and water level contour maps are discussed in the following sections.

#### 3.3.4.1. Water Levels in the Paso Robles Aquifer

As shown on Figure 6, water levels in the Paso Robles Aquifer (PCA East – Shallow) have fluctuated between about minus 1 foot below msl to about 7 feet above msl over the last 24 years. Water levels declined below sea level in the mid-1990s in response to increases in groundwater production. Most of the subsequent groundwater production occurred in the deeper Santa Margarita Aquifer and water levels in the Paso Robles Aquifer rose near the coast. Since that time, water levels in the PCA well have stabilized at about two to seven feet above msl. However, water levels remain below msl farther inland where a pumping depression persists (Figure 8).

An additional hydrograph for the Paso Robles Aquifer is shown on the top graph on Figure 7. Water levels in FO-7 (shallow curve shown in orange) illustrate water table conditions about 3,000 feet north of the Proposed Project Injection Well Facilities. Since 1994, the water table in FO-7 has declined from elevations above 20 feet msl in the mid-1990s to about 15 feet msl and have averaged 14.5 feet since 2006 (Figure 7). This decline is consistent with

---

[6] The level to which water rises in a well.

downgradient pumping in both aquifers that has created a localized pumping depression in the Northern Coastal Subarea.

Figure 8 shows the pumping depression by the closed contour of 0 feet msl (sea level) on the water level contour map (contours from HydroMetrics, 2013). This map, representing water levels measured in July and August 2013, shows water levels below msl covering an area of almost 1,000 acres (also covering about one-half of the Northern Coastal Subarea). Groundwater flow in both the Northern Coastal and Northern Inland subareas is controlled by the depression. Shallow groundwater beneath the Proposed Project Injection Well Facilities area flows west toward the center of the depression where water levels are lower than - 40 feet below msl.

The map also shows that the water levels in the adjacent Southern Coastal Subarea are not significantly influenced by the pumping depression. Contours in that subarea indicate westerly groundwater flow toward the coast and provide some evidence of compartmentalization of the groundwater system across the subarea boundary.

#### 3.3.4.2. Water Levels in the Santa Margarita Aquifer

Water levels have declined in the Santa Margarita Aquifer at a much faster rate than in the Paso Robles Aquifer. As shown on Figure 6, the potentiometric surface of the semi-confined Santa Margarita Aquifer indicates a long-term decline in the PCA East (Deep) well since the mid-1990s with only seasonal recovery. The high rate of decline is likely related to both the increase in Santa Margarita Aquifer pumping as well as the lower S value of the semi-confined aquifer. In general, the rate of decline has been less since about 2006 as a result of the adjudication of the groundwater basin and subsequent changes in pumping rates. Nonetheless, water levels have been below sea level in the coastal PCA East (Deep) well since 1995, increasing the risk of seawater intrusion.

Figure 7 shows similar trends and fluctuations on two hydrographs from Santa Margarita wells closer to the Proposed Project Injection Well Facilities area (FO-7 is about 3,000 feet north and Paralta Test Well is about 1,300 feet to the northwest, see Figure 8 for well locations). Water levels in the Paralta Test Well are generally higher than in FO-7 (Deep), likely due to the well screens installed in both the Paso Robles and the Santa Margarita Aquifers. Although the trends and fluctuations are more similar to the Santa Margarita water levels, the contribution from the Paso Robles Aquifer would raise overall water levels in the well. Water levels in the Paralta Test Well show greater seasonal fluctuations than observed in FO-7 due to its proximity to large pumping wells (Figure 7).

Figure 9 shows the widespread area of water level declines on a recent water level contour map for the Santa Margarita Aquifer (contours from HydroMetrics, 2013). The map shows that water levels are below msl over almost all of the Northern Coastal Subarea and a large portion of the Northern Inland Subarea. The lowest water levels are below -40 feet msl, similar to the low levels in the Paso Robles Aquifer (Figures 6 and 7). Water levels beneath the Proposed Project Injection Well Facilities area range from about -10 feet msl to about -30 feet msl.

The water level contour map also indicates that the pumping depression extends beyond the northern basin boundary but does not extend into the Southern Coastal subbasin. Similar to conditions in the Paso Robles Aquifer, groundwater in the Santa Margarita Aquifer in the Southern Coastal Subarea appears to be compartmentalized by geologic faulting and relatively unaffected by pumping to the north.

#### 3.3.5. Proposed Project Target Aquifers

Hydrogeologic and groundwater data indicate that both aquifers in the Seaside Basin could be recharged to increase basin yield. As shown by the water level contour maps in Figures 8 and 9, water levels in both aquifers have fallen below sea level, placing them both at risk for seawater intrusion.

To increase the basin yield and well production as envisioned in the Proposed Project, replenishment would occur to prevent adverse impacts on basin water levels. If an aquifer is pumped but not directly recharged, water levels may exhibit a short-term decline in one aquifer and a rise in the other. Although most of the groundwater production (and corresponding water level declines) has occurred within the Santa Margarita Aquifer, numerous production wells are also screened in the Paso Robles Aquifer.

These and other considerations for incorporating each aquifer into the Proposed Project are summarized in Table 4. Relative benefits and limitations are listed for comparison between the two aquifers. Issues are focused on the ability to recharge the Proposed Project's recycled water in a cost effective manner in order to allow basin yield to be increased. Based on the information discussed above and summarized in Table 4, the Proposed Project would include recharge into both of the basin aquifers.

**Table 4. Aquifer Considerations for the Proposed Project Injection Well Facilities Site**

| Issue | Paso Robles Aquifer | | Santa Margarita Aquifer | |
|---|---|---|---|---|
| | Relative Benefit | Relative Limitation | Relative Benefit | Relative Limitation |
| **Aquifer Characteristics** | Relatively shallow and thick aquifer. | More heterogeneous, interebedded with low permeability units, lower sand content, and lower hydraulic conductivity (K) values. | More permeable and homogeneous with a larger percentage of sand and higher K values. | Deep aquifer, occurring at depths greater than 600 feet locally. |
| **Groundwater Occurrence and Recharge Methods** | Unconfined groundwater allows for surface recharge. Deep water table creates large storage volume. Some downward leakage recharges underlying Santa Margarita Aquifer. | Interbeds limit downward migration of recharge in some areas. Lower K values limit injection capacity. Local test wells only capable of injecting about 350 gpm. | Semi-confined groundwater will respond more quickly to the same amount of recharge than in the shallower unconfined aquifer. High K values allow for high injection capacity. Local ASR wells inject >1,000 gpm. | Semi-confined groundwater has less storage. Direct recharge will require relatively expensive deep injection wells. |
| **Water Levels and Recovery of Product Water** | Water levels below sea level over large area. Several downgradient production wells screened in both aquifers. | Water level declines occur over a smaller area than Santa Margarita declines. Fewer wells are screened in the Paso Robles Aquifer. | Water levels declines are more severe, cover a larger area, and are below sea level throughout the Northern Coastal Subarea. | May require more coordination with nearby ASR operations. |

#### 3.3.5.1. Groundwater Modeling for Aquifer Allocation

The amount of recycled water from the Proposed Project allocated to the Paso Robles Aquifer and the Santa Margarita Aquifer can be varied to meet a variety of Proposed Project objectives including increasing basin yield, raising water levels, and providing adequate underground retention time of recycled water to meet regulatory requirements (see Section 4.1.4). The primary objective of the Proposed Project is to replenish the groundwater basin in a manner that allows for increased production in existing basin wells.

To support project planning, HydroMetrics applied the Watermaster groundwater model to determine the optimal allocation of recycled water injection between the two aquifers. Criteria for determining the optimal allocation included the following:

- capability of existing drinking water wells to capture the recharged recycled water
- minimizing loss of injected recycled water to ocean outflow
- balancing inflows and outflows with no groundwater storage changes.

A TM prepared by HydroMetrics documents the modeling assumptions and results. That TM is provided in Appendix B of this report (HydroMetrics, October 2013). Three scenarios were simulated as summarized in Table 5 below.

**Table 5. Aquifer Allocation of Recharge Water in Model Scenarios**

| Model Scenario | Paso Robles Recharge | Santa Margarita Recharge |
|---|---|---|
| 1 | 100% | 0% |
| 2 | 0% | 100% |
| 3 | 20% | 80% |

Based on the results of the modeling and application of evaluation criteria, an aquifer allocation between 80 percent and 100 percent of recharge to the Santa Margarita Aquifer (accompanied by 20 percent to 0 percent of recharge to the Paso Robles Aquifer) was judged optimal to allow increased production with minimal impacts to basin storage. Based on these results, the following recycled water injection allocations were proposed: 90 percent for the Santa Margarita Aquifer and 10 percent for the Paso Robles Aquifer. This allocation also approximates the production allocation from each aquifer screened in existing production wells.

### 3.3.6. Methods Considered for Groundwater Recharge

In order to select the most cost effective groundwater recharge method for the Proposed Project, Todd Groundwater examined various recharge methods for both aquifers. A summary of this examination is provided in the subsequent sections.

#### 3.3.6.1. Paso Robles Aquifer Recharge Method

Several recharge methods were considered for recharge into the Paso Robles Aquifer: surface recharge basins, vadose zone wells, and deep injection wells.

##### *3.3.6.1.1. Surface Recharge Methods*

Surface recharge basins were considered for the Proposed Project, given their long performance record in California and relative ease of construction and maintenance. However, surface recharge basins capable of recharging the total amount of water for the Proposed Project would require a large surface area of relatively flat land (estimated at about 10 acres) in a hydrogeologically-favorable location. MRWPCA determined that purchase of such a large parcel in the project area would be very expensive, even if land could be located. Even though recharge into the Paso Robles Aquifer was eventually allocated to be only a small percentage of project water, a surface basin would have a larger visual impact than using subsurface methods such as injection wells. In addition, subsurface methods can be spaced for minimal overall land disturbance. Also, the travel time for recharge water to reach the aquifer would be maximized in surface basins. For these and other reasons, surface recharge methods were eliminated from further consideration.

##### *3.3.6.1.2. Deep Injection Wells*

Deep injection wells for the Paso Robles Aquifer recharge were considered but eliminated after a hydrogeologic review of a test injection well that had been installed near the Proposed Project Injection Well Facilities. Specifically, MPWMD drilled a Paso Robles test injection well, PRTIW, for potential storage and recovery of surface water in the Paso Robles Aquifer. PRTIW is located west of General Jim Moore Boulevard across from the ASR-1 wellfield (Figure 2).

Injection testing in PRTIW indicated relatively low injection rates of approximately 350 gpm (compared to the nearby ASR Project and Proposed Project wells in the Santa Margarita Aquifer, which are expected  inject approximately 1,000 gpm), due to the lower hydraulic conductivity of the aquifer. The rate was deemed inadequate for an economical injection well by MPWMD, and the well is now being used for monitoring and for extracting water for irrigation supplies. Even though injection of 350 gpm might be considered an acceptable rate for the Proposed Project, it is unlikely that such a rate could be sustained on a long-term basis. Because of the heterogeneity and overall lower permeability in the Paso Robles Aquifer, injection capacity is likely to decrease more rapidly than in the more permeable Santa Margarita Aquifer. Lower permeability aquifers can be more susceptible to physical and biological processes that clog pores and restrict groundwater flow.

##### *3.3.6.1.3. Vadose Zone Wells*

A vadose zone well is an injection well installed in the unsaturated zone above the water table. These wells typically consist of a large-diameter borehole with a casing/screen assembly installed with a filter pack. The well is used as a conduit for transmitting water into the subsurface, allowing infiltration into the vadose zone through the well screen and percolation to the underlying water table. Creating this pathway is advantageous for replenishment projects where surficial soils or the shallow subsurface contain clay layers or other low permeability impediments to deep percolation. Vadose zone wells allow replenishment water to bypass shallow layers, reaching the water table faster and along more direct pathways. In addition, replenishment water quality can potentially benefit from soil-aquifer treatment (SAT) in the lower vadose zone prior to arrival at the water table.

Historically, vadose zone wells have been used in the U.S. with varying success, primarily functioning as disposal wells, or “dry wells” and often used for lower quality wastewater or stormwater. The primary disadvantage to using vadose zone wells is the difficulty of repairing wellbore/aquifer damage from physical or biological clogging once it occurs in the well. Typical well development and rehabilitation techniques cannot be conducted on wells screened in the vadose zone. However, the high quality recycled water anticipated for injection for the Proposed Project would be less likely to create potential clogging. Further, design specifications can be incorporated to mitigate clogging and other factors that decrease well performance such as air entrainment.

Over the last 15 years, vadose zone wells have been used successfully in similar areas for recharging recycled water. In particular, the City of Scottsdale, Arizona operates approximately 35 active vadose zone wells (with 27 additional backup wells) for groundwater recharge of recycled water at their Water Campus. Recharge capacity on a per well basis averages about 200 gpm to 400 gpm with some wells capable of injection rates higher than 1,000 gpm. Wells are spaced about 100 feet apart. MRWPCA visited the City to review details of the project. City technical staff provided information and data from these wells in support of the Proposed Project (City of Scottsdale, personal communication, July 16, 2007; July 27, 2007).

Some of the advantages and disadvantages of using vadose zone wells are listed below. Advantages of incorporating vadose zone wells into the Proposed Project include:

- greater certainty of migration pathways into the subsurface compared to surface basins
- ability to by-pass shallow low permeability layers, if any
- less land requirement than surface recharge basins
- no evaporation losses
- less expensive to construct compared to injection wells.

Some disadvantages of using vadose zone wells include:

- limited methods to develop or rehabilitate wells to address lost capacity due to clogging
- limited recharge rates
- air entrainment can reduce recharge capacity if wells are not operated properly.

Because of prior data gaps associated with the physical characteristics and recharge capability of the deep vadose zone at the Proposed Project Injection Well Facilities site, the MRWPCA field program focused on core samples and laboratory analyses throughout the vadose zone to about 130 feet below the water table. Results of the field program and laboratory analyses were used to confirm design features of the vadose zone wells for the Proposed Project (Section 4.2). Complete results of the vadose zone characterization are documented in a separate report on the field program (Todd Groundwater, February 2015).

#### 3.3.6.2. Santa Margarita Aquifer Recharge Method

Due to the semi-confined groundwater conditions in the Santa Margarita Aquifer, deep injection wells are the only viable method for groundwater replenishment. Although some vertical natural recharge occurs from the Paso Robles Aquifer into the Santa Margarita Aquifer, the amount and timing are uncertain. As noted above (Section 3.3.3.3), most of the extraction in the Northern Coastal Subarea is from the Santa Margarita Aquifer. Direct injection into the aquifer would allow for immediate benefits to water levels in that aquifer and allow downgradient wells to recover the recycled water in a more direct manner.

Successful use of deep injection wells in the Santa Margarita Aquifer has already been demonstrated at the nearby MPWMD ASR Project. Located only about 1,000 feet to 1,600 feet from the Proposed Project Injection Well Facilities site, these wells provide site-specific information on aquifer properties, injection capacity, well design, and costs. According to MPWMD, ASR wells are capable of sustaining injection rates of 1,000 gpm to 1,500 gpm. Testing data in ASR-1 indicated a T value of 104,325 gallons per day per foot (gpd/ft) and a specific capacity of 55 gallons per minute per foot of drawdown (gpm/ft) dd (Padre, 2002). Collectively these data, along with ongoing operational data, indicate that only three to four deep injection wells (allowing for down time associated with well maintenance) would be needed for the Proposed Project to recharge recycled water, a number that is feasible for the Proposed Project.

In addition to these site-specific data, there are four operating groundwater replenishment injection projects in California that have demonstrated the viability of long-term deep injection of recycled water. One example is the project implemented by the Orange County Water District (OCWD). For more than 36 years, OCWD has injected recycled water (and diluent water until 2008) into the Talbert Barrier, a line of more than 40 injection wells creating a hydraulic barrier to seawater along the Orange County coast. A second example is the West Coast Basin Barrier Project in nearby Los Angeles County, where recycled water (and potable water) has been injected into aquifers associated with the West Coast Basin Barrier Project since 1995. The barrier consists of an 8-mile line of about 150 injection wells from the Los Angeles airport to the Palos Verdes peninsula. Both projects have replenished various aquifers, increased the sustainable yield of the basins, and impeded the further intrusion of seawater.

## 4. PROPOSED PROJECT WELLS

The conceptual layout and preliminary design for the Proposed Project wells are based on the amount of recycled water available for replenishment (see Section 2) and the local hydrogeology (see Section 3). General specifications suggested for the two types of injection wells (vadose zone well and deep injection well) are summarized in Table 6.

### Table 6. Proposed Project Well Specifications

| Potential Project Specification[1] | Paso Robles Aquifer | Santa Margarita Aquifer |
|---|---|---|
| **Depth to Aquifer Top** | 371 feet | 623 feet |
| **Depth to Aquifer Bottom** | 623 feet | 903 feet |
| **Depth to Water** | 382 feet | 404 feet |
| **Recharge Method** | Vadose Zone Well | Deep Injection Well |
| **Groundwater Occurrence** | Unconfined | Semi-Confined to Confined |
| **Transmissivity** | 659 to 1,524 $ft^2$/day | 11,377 to 13,947 $ft^2$/day |
| **Hydraulic Conductivity** | 20 ft/day | 63 ft/day |
| **Number of Wells** | 4 | 4 |
| **Injection Capacity per well** | 500 gpm | 1,000 gpm |
| **Total Injection Capacity** | 2,000 gpm | 4,000 gpm |
| **Extraction Capacity per well (for well maintenance)** | NA | 2,000 gpm |

[1] Assumes project well configuration as shown on Figure 2 with an average ground surface elevation of 379 feet, mean sea level (msl). Depths are average depths for all wells.
$ft^2$/day – square foot per day; gpm = gallons per minute; NA – not applicable

The injection wells would be constructed on a parcel of land (APN-031-211-001-000) that is currently owned by FORA and scheduled for re-conveyance to the City of Seaside (City). This conceptual project configuration has been presented to the City in informational meetings but has not yet been formally approved by FORA or the City. The City, through its Municipal Code Ordinance, has placed prohibitions and restrictions on construction of wells on certain FORA parcels. However, the Proposed Project Injection Well Facilities would be located on a parcel that is not on the City's prohibited/restricted construction list. The only Municipal Code restriction for this parcel involves soils management during construction activities, which would be readily incorporated into the Proposed Project well Technical Specifications and drilling program requirements.

The Proposed Project injection well locations are shown on Figure 10 along with other project components including back-flush basins and monitoring wells. Estimated ground surface elevation, depth to water and the aquifers encountered in each proposed well are presented in Table 7.

## Table 7. Proposed Project Wells

| GWR PROJECT WELLS | GSE[1] | Groundwater Elevation[2] | Depth to Water | Paso Robles[3] | | Santa Margarita | | Well Depth |
|---|---|---|---|---|---|---|---|---|
| | | | | Depth to Top | Depth to Base | Depth to Top | Depth to Base | |
| | ft, msl | ft, msl | ft, bgs | ft, bgs | ft, bgs | ft, bgs | ft, bgs | ft, bgs |
| **Santa Margarita Deep Injection Wells (DIW)** | | | | | | | | |

## 4.1. DEEP INJECTION WELLS

Key considerations for the design of Proposed Project deep injection wells include:

- sufficient capacity to accommodate delivered recycled water from the AWTF
- sufficient number of wells to plan for well maintenance and repairs offline
- adequate well spacing to minimize hydraulic mounding interference with other project wells or nearby ASR Project wells
- location sufficiently close to existing production wells to allow the efficient recovery of recycled water
- location with sufficient distance from downgradient production wells to comply with regulatory requirements regarding response and retention times (see Section 4.1.4).

These proposed design considerations are summarized in the following sections.

### 4.1.1. Deep Injection Well Capacity

Although MPWMD has installed four successful deep injection (and recovery) wells at the nearby ASR Project, the manner in which the Proposed Project deep injection wells would be operated may result in a slightly different well capacity than the ASR wells. Compared to the ASR Project wells, the Proposed Project wells would receive recycled water on a more continuous basis, would inject water at a more consistent rate over time, and would not be used for recovery of injected water (which would be accomplished through existing downgradient production wells). Injection wells would only be pumped (backwashed) periodically for well maintenance.

In consideration of these factors, a design injection rate slightly lower than the ASR Project wells has been selected for the Proposed Project. Injection capacity at the nearby ASR wellfield is estimated at approximately 1,500 gpm/well. Therefore, a slightly more conservative injection rate of 1,000 gpm/well is estimated for the Proposed Project. This rate would minimize local mounding and long-term stress on the wells.

#### 4.1.2. Number of Deep Injection Wells

Table 1 (in Section 2) presents potential recycled water delivery schedules to provide an average of 3,500 AFY and a maximum of 3,700 AFY of recycled water for Seaside Basin recharge. A key criterion is that the deep injection wells must be capable of accepting the maximum daily injection rate for recycled water from the AWTF for the Santa Margarita Aquifer. As shown in Table 1, the maximum rate for Santa Margarita injection is estimated at 2,179 gpm. With an injection capacity of 1,000 gpm/well, a minimum of three deep injection wells with total design capacity of 3,000 gpm would be required.

Although three wells appear to have sufficient capacity to handle the proposed recycled delivery schedules, extra injection capacity would be desirable to account for well maintenance/down time and potential decreases in well capacity over time. For planning purposes, an injection well is assumed to be operational about 80 percent of the time. Although decreasing injection capacity with time would be managed through well maintenance (back-flushing), the exact maintenance schedule is difficult to predict. Because a well might be down for maintenance (or other reasons) at a time when the maximum injection rate would be required, it is reasonable to incorporate a fourth deep injection well into the Proposed Project.

Accordingly, a total of four deep injection wells are proposed for the project, designated as DIW-1 through DIW-4 on Figure 10. The four proposed wells would provide a total operational capacity of 4,000 gpm, allowing capacity to be reduced to 3,000 gpm when any one well goes offline.

#### 4.1.3. Location and Spacing of Deep Injection Wells

As shown on Figure 10, the deep injection wells have been sited with approximately 1,000 feet between Proposed Project wells. A minimum 1,000-foot spacing is also maintained between each Proposed Project well and the closest downgradient well. There are technical and regulatory considerations for the location and spacing of these wells. Because the injection wells would be operated continuously (except during routine maintenance), water levels are expected to rise or “mound” around the injection wells and expand over time until steady state conditions are reached. As these groundwater mounds overlap in the subsurface, groundwater gradients increase and injection rates may decrease as the well becomes less efficient. Increased spacing between wells (based on the aquifer’s hydraulic properties) can minimize the impacts of this hydraulic interference. In addition, spacing between the injection wells and downgradient production wells is considered to balance the timely recovery of recharged water with longer retention times required by state regulations (see section 4.1.3.2). These considerations are discussed in more detail below.

#### 4.1.3.1. Hydraulic Interference

For the four deep injection wells that target the same confined aquifer, the proposed well spacing considers the potential for hydraulic interference due to groundwater mounding. Preliminary modeling conducted in 2005 for the CalAm ASR Project indicated that well spacing of about 1,000 feet between wells screened in the Santa Margarita Aquifer would result in only minor interference (ASR Systems, April 2005). Because the hydraulic properties assumed for that modeling are similar to those anticipated beneath the project Injection Well Facilities site, the 1,000-foot spacing is incorporated for the Proposed Project. By moving wells back to the edge of the parcel, the Proposed Project wells would also retain 1,000 feet spacing from the ASR wellfields to minimize interference with ASR operation.

#### 4.1.3.2. Response Retention Time

The SWRCB Division of Drinking Water (formerly the California Department of Public Health) has adopted Groundwater Replenishment Regulations (SWRCB Regulations) for the recharge of recycled water (SWRCB, June 2014). The SWRCB Regulations contain requirements for underground retention time of recycled water that could also potentially affect well spacing. For example, recycled water must be retained underground for a sufficient period of time (as proposed by a project sponsor as part of the California Water Code project permitting[7]) to identify and respond to any treatment failure so that inadequately treated recycled water does not enter a potable water system (referred to as the response retention time). The response retention time has to be at least two months. The 1,000-feet distance between Proposed Project wells and the closest downgradient production wells is expected to result in a travel time of approximately one year. Therefore, the proposed configuration of the Proposed Project wells would readily meet the minimum required response retention time.

#### 4.1.3.1. Underground Retention Time

Additional requirements in the SWRCB Regulations were also considered for well locations and spacing. According to the SWRCB Regulations, a groundwater replenishment project must achieve a 12-log enteric virus reduction using at least three treatment barriers, one of which can be underground retention time with a 1-log reduction per month up to 6 months (6-logs). Notwithstanding the effectiveness of the RTP and AWTF in controlling pathogens, the Proposed Project includes a conservative goal of achieving up to a 6-log virus reduction credit by keeping the recycled water underground for six months prior to arrival at the closest downgradient production wells (ASR-1, ASR-2, and City of Seaside 4 – see Figure 10).

This underground retention time will be demonstrated through a field tracer test after project implementation in compliance with the SWRCB Regulations. For planning purposes, the Watermaster groundwater model has been used to predict or estimate underground retention times for Proposed Project wells. When a model is used to demonstrate the travel

[7] This process includes submittal of an Engineering Report for approval by the SWRCB Division of Drinking Water and review by the CRWQCB.

time, the required retention time is doubled to account for uncertainty in the method of analysis as required by the SWRCB Regulations. Therefore, the model needs to demonstrate a travel time of one year to allow for a six-month credit. Preliminary modeling indicates that seven of the eight Proposed Project wells would meet the one year requirement needed to assume a 6-log virus reduction credit prior to a tracer test. However, modeling indicates that recycled water injected into one injection well, DIW-3, could reach ASR-1 in less than one year (shortest time of 327 days) under certain pumping conditions during five years of the 25-year simulation period. The fastest travel time of 327 days is 38 days short of the model-based one-year travel time project planning goal.

While the necessary underground retention time of six months remains applicable to the Proposed Project, a tracer test, rather than modeling alone, will be needed to demonstrate the project can meet the underground retention time to claim a 6-log reduction credit. Until that test can occur, it is assumed for planning purposes that the estimated minimum 10.5 to 11 months travel time from DIW-3 to the nearest extraction well will limit the reduction credit to a 5-log credit for the Proposed Project. For the conservative purposes of the EIR analysis, it is anticipated that a 5-log reduction credit can be achieved based on modeling results and future revisions would be based on an actual tracer test that is initiated after project startup. Model results are discussed in detail in Section 7. Documentation of the particle tracking associated with the modeling of the Proposed Project is provided in the TM by HydroMetrics (January 2015), included in this report as Appendix C.

#### 4.1.4. Preliminary Deep Injection Well Design

Incorporating some of the successful design features already tested in MPWMD ASR wells, a preliminary well design for a Proposed Project deep injection well has been developed. The exact well depth and screen placement may be determined based on field results during project construction. Current design criteria are summarized in Table 8. A preliminary deep injection well construction diagram is shown on Figure 11.

### Table 8. Summary of Design Criteria For Proposed Project Injection Wells

| Component/Parameter | Criteria |
|---|---|
| Number of Santa Margarita injection wells | 4 |
| Average depth to water | 400 feet |
| Injection rate per well | 1,000 gpm |
| Discharge rate per well | 2,000 gpm |
| Average well depth | 909 feet |
| Casing size and materials | 18-inch outer diameter (OD) stainless steel |
| Screen assembly | 230 feet stainless steel wirewrap |
| Pump for back-flush | 400 horse power (Hp) |

## 4.2. VADOSE ZONE WELLS

Similar to deep injection wells, well capacity and well spacing are also key considerations for vadose zone wellfield design. However, pathways and transport of the product water from the AWTF are also important considerations. Recent data from the MRWPCA field program was used to analyze a preliminary vadose zone well design and operational parameters for the Proposed Project. Complete results of the field program are presented in a separate report (Todd Groundwater, February 2015). For planning purposes, the vadose zone well layout is shown on Figure 10 and discussed in more detail below.

### 4.2.1. Well Capacity

MRWPCA collected site-specific data during the 2013-2014 field program to better assess potential injection capacity and optimize well design for recharging the Paso Robles Aquifer. Based on core samples and geologic logging in MRWPCA MW-1, the vadose zone appears more homogeneous and permeable than the saturated zone of the Paso Robles Aquifer. Hydraulic conductivity data from core samples indicate the potential for high injection rates. An analysis of vadose zone well capacity presented in the field program report (Todd Groundwater, February 2015) indicated that one vadose zone well could likely recharge the entire allocation of 242 gpm. The analysis suggests that with about 100 feet of screen, an injection rate of approximately 500 gpm could be achieved. This analysis is supported by the large storage capacity in the vadose zone beneath the Proposed Project Injection Well Facilities site.

Thin, low-permeability silt and clay zones were more prevalent in the lower portions of the vadose zone that could potentially decrease injection rates or result in long travel times to the water table. A comparison of these zones with geologic descriptions in the closest production wells (Reservoir Well and PRTIW) indicate that these layers are not likely continuous over the Proposed Project Injection Well Facilities area.

### 4.2.2. Number of Wells

With an estimated injection capacity of 500 gpm, only one vadose zone well would be needed to accommodate the anticipated delivery of product water. As shown in Table 1 (Section 2), the maximum injection rate estimated for the Paso Robles Aquifer is 242 gpm.

However, more than one well is recommended for several reasons. First, the long-term injection capacity of vadose zone wells is uncertain and may also represent very long travel times. Vadose zone wells are subject to clogging and cannot be redeveloped using conventional techniques. Vadose zone wells are much less expensive than deep injection wells and can be incorporated into the Proposed Project at a much lower cost. In addition, the extra capacity would provide the Proposed Project with operational flexibility. If unanticipated well problems arise, additional vadose zone capacity would allow injection to continue while wells are being repaired or replaced. If monitoring indicates that certain target recharge areas are being under-supplied to the Paso Robles Aquifer, additional vadose zone wells would allow recharge to be targeted in specific areas. Accordingly, four vadose zone wells are being incorporated into the Proposed Project design.

#### 4.2.3. Spacing and Location of Wells

The locations of the vadose zone wells along the 3,000 feet corridor are less sensitive to the criteria for placing the deep injection wells with respect to the distance to the nearest downgradient production well. In particular, vadose zone wells are less sensitive to the requirement for underground retention time described previously (Section 4.1.3.1). Average linear groundwater velocities are lower in the Paso Robles Aquifer due to lower permeability, which adds to the travel time to production wells. In addition, travel time is lengthened by the additional time needed for water to percolate from vadose zone well screens to the water table.

In addition, the spacing between wells is considered less critical for hydraulic interference than deep injection well spacing, given the large storage volume in the vadose zone and the relatively small amounts of injection planned for the vadose zone wells. Well spacing at the Scottsdale Water Campus was only a few hundred feet for wells of similar depth and injection rates as the Proposed Project. Further, there is no spacing requirement between deep injection wells and vadose zone wells because they are recharging separate aquifers.

For planning purposes, it is proposed that one vadose zone well would be placed next to each of the four deep injection wells, resulting in a well spacing of 1,000 feet between vadose zone wells (Figure 10). This configuration provides some construction and operational conveniences in that deep and shallow wells are in close proximity for monitoring and maintenance.

#### 4.2.4. Preliminary Well Design

Based on the above analysis of the Proposed Project, a preliminary vadose zone well design has been developed. The preliminary well design incorporates some of the appropriate design features from the City of Scottsdale's successful vadose zone wells including well and casing diameter and materials. Most of the City of Scottsdale's recent wells consist of a 30-inch to 48-inch diameter borehole containing a 12-inch to 18-inch PVC casing/screen assembly with approximately 100 feet of slotted screen. Wells were typically drilled to a depth of 150 to 180 feet and installed with a filter pack from the bottom of the well up to a surface seal. The vadose zone beneath Scottsdale consists of permeable alluvial sediments with the water table at a depth of approximately 400 feet, conditions similar to the Proposed Project Injection Well Facilities site (City of Scottsdale, personal communication, July 27, 2007).

One of the early operational problems experienced by the City of Scottsdale was lost capacity due to air entrainment, a situation remedied by maintaining a full water column in the recharge pipe and preventing cascading water in the well (Marsh, et al., 1997). Casing failures also have occurred in some wells and appear to correlate to the placement and operational pressure of the injection line at the well screen (City of Scottsdale, personal communication, July 16, 2007).

Over time, the City of Scottsdale has modified their well design to install one or more small-diameter recharge lines to the bottom of the well (e.g., a 4-inch PVC casing referred to as an eductor line). The well design also incorporates transducer tubes, ventilation lines, and lines to access the gravel pack (City of Scottsdale, personal communication, July 27, 2007). These three additional components allow for more accurate monitoring, less chance of air entrainment, and ability to add to the gravel pack, respectively.

Based on the information reviewed from the Scottsdale vadose zone wells and site-specific conditions investigated during the recent MRWPCA field program, design criteria have been developed for the Proposed Project wells as summarized in Table 9. A preliminary vadose zone well construction diagram is provided on Figure 12.

**Table 9. Summary of Design Criteria for Proposed Vadose Zone Wells**

| Component/Parameter | Criteria |
|---|---|
| Number of wells | 4 |
| Depth to water table | 380 feet |
| Borehole diameter | 48 inches to 150 feet; 30 inches to 200 feet |
| Casing/Screen diameter | 18-inch OD PVC with 100 feet slotted casing (100 slot) |
| Injection | 4-inch OD PVC eductor line |
| Injection capacity | 500 gpm |
| Annular material | Artificial filter pack or gravel |
| Monitoring equipment | Transducer |

## 4.3. Well Maintenance and Back-flushing Operations

Deep injection wells would need to be pumped periodically to maintain injection capacity, a process known as back-flushing. Injection rates typically decrease with time as a result of numerous conditions that can clog the well such as air entrainment, filtration of suspended or organic material, bacterial growth, precipitates due to geochemical reactions, swelling of clay colloids, dispersal of clay particles due to ion exchange, and/or mechanical compaction of aquifer materials (Fetter, 1988). Clogging rates are often directly related to the presence of solids in the recharge water and indirectly related to the permeability of the aquifer (i.e., higher clogging rates are typically correlated to lower permeability aquifers). Pumping reverses the flow in the well, alters the geochemical environment, and dislodges some of the clogging particles.

### 4.3.1. Back-flushing Rates and Schedule

Back-flushing is typically conducted at pumping rates higher than injection rates. In a plugging survey published by Pyne (2005), injection rates averaged about 75 percent of extraction rates, but that percent varied widely from project to project. At the nearby ASR Project, MPWMD back-flushes the wells at about twice the injection rate. For planning purposes, it is assumed that the Proposed Project would also back-flush the deep injection wells at twice the injection rate. Accordingly, the deep injection wells would be designed for an injection rate of 1,000 gpm, and back-flushing would be conducted at 2,000 gpm.

The optimal back-flushing schedule and required pumping volumes would be determined once the injection wells are operational. At one Arizona project, injection well operators found that frequent pumping for short periods on a daily basis was the most effective schedule for re-establishing declining capacity (Bouwer, 2002). Other operators have found monthly pumping to be adequate.

The nearby MPWMD ASR wellfield site contains a small back-flush basin that holds approximately 240,000 gallons of water to accommodate several hours of weekly pumping. Because the Proposed Project recycled water will contain relatively low suspended or total dissolved solids (TDS), clogging rates of the deep injection wells may be lower than observed at nearby ASR wells. However, because the Proposed Project wells are being completed in the same aquifer as the ASR wells, and because the injectate for the ASR Project is also relatively low in solids content, weekly pumping is being assumed for planning purposes. Regardless of the pumping frequency, a facility for retention and recharge of the discharged water would be constructed.

For planning purposes, a back-flush schedule similar to the one established at the nearby ASR wellfields would be incorporated into the Proposed Project. The ASR operations suggest that the proposed deep injection wells would be pumped for approximately four hours each on a weekly basis at a pumping rate of 2,000 gpm (twice the estimated injection rate). The actual amount of backflushing would be based on operational needs established in the field, but this schedule represents a reasonable maximum for evaluation of potential impacts. This schedule would produce approximately 480,000 gallons per well per week for discharge into a back-flush basin.

### 4.3.2. Back-flush Basin Location

In order to facilitate the back-flushing operation, a small surface basin would be constructed near the Proposed Project wells. Water would be piped to the basin, allowed to infiltrate the permeable sediments on the open basin bottom, and percolate down to the water table. By allowing the water to recharge, pumped water would be conserved. This approach for infiltration of back-flushed water was conceptually approved by the SWRCB Division of Drinking Water (Division of Drinking Water, 2014). A preliminary design of the basin and other back-flushing appurtenances has been conducted for MRWPCA by E2 Consulting Engineers.

Several sites have been considered for the proposed back-flush basin location. Although only one site would be needed to support the Proposed Project, three potential sites are shown on Figure 10. The northeastern-most site is the preferred location for the Proposed Project due to its proximity to DIW-1 and DIW-2, the two wells likely to be installed first during the construction phase of the project. The northeastern basin location is also situated on a relatively flat area along the comparatively steep grade of the Proposed Project area.

Two alternate basin sites have been conceptualized at the southern portion of the Proposed Project Injection Well Facilities site near General Jim Moore Boulevard. One site is of similar design to the northeastern basin alternative and is situated at the lowest ground surface elevation of the Proposed Project Injection Well Facilities area (refer to the southern area of blue shading on Figure 10). That basin would be capable of receiving and recharging back-flush water from the Proposed Project wells via a gravity-flow pipeline.

A third location for a back-flush basin is identified northwest of the second location and within 100 feet of General Jim Moore Boulevard. This larger, and potentially deeper basin, was originally identified by MPWMD as an alternative site for back-flush water from the ASR Project wells. The basin is located within a natural depression, referred to as the San Pablo depression due to its proximity to San Pablo Avenue (see Figure 10). Discussions between MPWMD and MRWPCA indicated that there may be some efficiency for sharing a back-flush basin. However, basin construction has not yet been approved and MPWMD has been considering other discharge options in addition to the San Pablo depression.

#### 4.3.3. Back-flush Basin Design

The basin would be constructed on the Aromas Sand, which comprises the upper 300- to 400-feet of vadose zone beneath the Proposed Project Injection Well Facilities area. This geologic unit was recently evaluated in a nearby monitoring well MRWPCA MW-1 (Figure 10). Core samples throughout the vadose zone were collected and analyzed for vertical permeability values to assist with the design. Laboratory permeability values vary widely from more than 100 feet per day in the most permeable sand zones to less than 0.01 feet per day in silty clay intervals. However, samples above about 277 feet contain very little fine-grained sediment (silt or clay). The lowest permeability value above that depth is about 14 inches per hour (or 28 feet per day). MPWMD corroborated this laboratory infiltration rate with observed infiltration rates of about one foot/hour during the first hour of discharge at the existing ASR back-flush basin (located between ASR-1 and ASR-2 and about 1,000 feet from the preferred Proposed Project back-flush basin location, see Figure 10).

Although the vertical permeability value of 28 feet per day may not translate into a long-term infiltration rate, the laboratory data and geologic core samples from MRWPCA MW-1 indicate that the upper 277 feet of the vadose zone is capable of rapid infiltration and storage of water discharged into a back-flush basin. Further, these rates suggest that the basins would be empty on a regular basis for drying and periodic tilling to break up any surficial clogging. For planning purposes, a conservative design infiltration rate of six feet per day is assumed. That rate is judged reasonable, given that it is only about 20 percent of the lowest permeability value recorded in the upper 277 feet of the vadose zone.

Based on these data, E2 Consulting Engineers has developed a preliminary design for the back-flush basin at the Proposed Project Injection Well Facilities site. The preliminary design covers a footprint of approximately 180 feet by 50 feet and would be located between DIW-2 and DIW-3 in the general vicinity of the northeastern-most location shown on Figure 10.

#### 4.3.4. Vadose Zone Wells and Back-flushing

Although vadose zone wells are also subject to clogging, they are constructed above the water table and cannot be readily back-flushed. The injection rate decline in those wells will not be known until the Proposed Project injection begins. However, there are many factors associated with the Proposed Project that would compensate for this potential issue. First, injection design rates are much smaller than indicated by recent permeability data for the Aromas Sand (Todd Groundwater, February 2015). Second, only about 10 percent of the total recycled water produced by the AWTF is currently planned for injection into vadose zone wells. With the assumed conservative injection rate and the smaller amounts of water available for injection, wells would not be needed full time and can dry between injection cycles. This would encourage die-off of any bacterial growth in the well. In addition, the Proposed Project recycled water would be highly treated with very low suspended or dissolved solids that could clog wells. Finally, more vadose zone wells are being incorporated into the Proposed Project than the anticipated volumes suggest are needed. If vadose zone wells are capable of 500 gpm as planned, four wells would provide a capacity of 2,000 gpm. However, a total capacity of only about 242 gpm is needed to handle the maximum amount of water allocated for the Paso Robles Aquifer (see Table 1). Collectively, these factors indicate that vadose zone wells can be incorporated successfully into the Proposed Project without back-flushing.

Even if all of the factors above are not sufficient to maintain injection capacity, there is the potential to install temporary equipment into the vadose zone wells to flush the annular space and pump out water that subsequently flows into the well. This method may be considered if injection rates in vadose zone wells cannot be sustained or managed with the number of wells proposed. The current design of the back-flushing detention basin would be capable of handling this small amount of extra water on a temporary basis if needed.

### 4.4. MONITORING WELLS

New monitoring wells and a monitoring well program are incorporated into the Proposed Project to demonstrate ongoing project performance and to comply with existing regulations. Objectives of the monitoring well program would be to comply with SWRCB and Central Coast Regional Water Quality Control Board (CRWQCB) regulatory requirements by:

- collecting baseline water quality samples prior to startup of the Proposed Project
- monitoring groundwater levels and water quality; the well design would allow for sample collection from each aquifer receiving recycled water
- siting one downgradient well with groundwater travel times (underground retention time) no less than two weeks and no more than six months from the Proposed

Project injection wells (well also has to be greater than 30 days travel time from the nearest drinking water source)

- siting an additional downgradient well between the Proposed Project Injection Well Facilities and the nearest downgradient potable water supply (in addition to the downgradient monitoring well used to demonstrate retention time).

The monitoring wells would also be used to collect data as part of the tracer study (or studies) to demonstrate an underground recycled water retention time of at least six months for a 6-log virus reduction credit and the response retention time that would be developed as part of the California Water Code project permitting process for the Proposed Project.

#### 4.4.1. Monitoring Well Locations

The number and location of appropriate monitoring wells will be negotiated with the SWRCB Division of Drinking Water and CRWQCB for the Proposed Project. Proposed monitoring wells would satisfy the regulations described above and allow for proper monitoring of project performance. After the completion of one field tracer test, results may eliminate the need for one or more monitoring wells located close to remaining injection wells. Further, it appears from preliminary particle tracking results that several injection wells could be monitored by one set of downgradient monitoring points. Nonetheless, the locations of the monitoring wells have not yet been optimized and approved by the SWRCB Division of Drinking Water or CRWQCB. Accordingly, two monitoring well locations for each of three injection well clusters are assumed for the purposes of the impacts analysis.

Following this conservative assumption, the Proposed Project could incorporate up to six downgradient monitoring wells in each aquifer (12 monitoring points) on the north, central, and south portions of the project area, resulting in monitoring wells at six locations (GWR MW-1 through GWR MW-6 on Figure 10). At each of the six monitoring well locations, two adjacent, but separate boreholes would be drilled in close proximity (within about 20 feet) of each other at the same location – one for the Paso Robles Aquifer and one for the Santa Margarita Aquifer (referred to as a well cluster). These six well clusters would result in 12 monitoring points at six locations. For simplicity, each well cluster is referred to as one monitoring well in the text and on the figures.

This monitoring well distribution would allow two downgradient well clusters between each of three injection wells (DIW-2, DIW-3, and DIW-4) and the closest production wells (ASR-1 and ASR-2 for DIW-2 and DIW-3 and Seaside No. 4 for DIW-4). Due to the location and distance of DIW-1 from the nearest downgradient well, GWR MW-2 would also provide monitoring of DIW-1 and no additional wells in the eastern project area are envisioned (Figure 10).

Three of the downgradient monitoring well clusters (GWR MW-1, GWR MW-3, and GWR MW-5) would be located within about 100 feet of three Proposed Project injection wells (DIW-2, DIW-3, and DIW-4) to allow near-injection monitoring and to accommodate tracer testing in compliance with the SWRCB Regulations (SWRCB, 2014). According to the regulations, the near-injection monitoring well would monitor subsurface transport times between two weeks and six months (SWRCB, 2014). This well can also serve as the monitoring well for an injectate tracer test. Three additional downgradient monitoring well clusters, GWR MW-2, GWR MW-4, and GWR MW-6, would be located about halfway between the Proposed Project and the nearest drinking water well in order to monitor groundwater conditions with more than 30 days of transport time away from the drinking water well (SWRCB, 2014).

MRWPCA MW-1 and FO-7 (shallow and deep) would provide upgradient data to support the monitoring program by serving as control wells (Figure 10). Sampling of these wells in January 2014 included an expanded analyte list to provide background water quality data.

## 5. WELL CONSTRUCTION ACTIVITIES

The field construction program involves construction and testing of the Proposed Project wells as described in this section. The actual timing of construction, equipping, and hook-up of the proposed wells would be coordinated with construction of the Proposed Project facilities being developed by others.

### 5.1. FIELD PLANNING

Prior to the initiation of the proposed well construction field program (referred to simply as field construction program in this section), numerous planning activities would be required including:

- identification of specific field activities
- sequencing and scheduling of events
- development of Technical Specifications for wells and the drilling and testing program
- selection of qualified contractors
- assistance to MRWPCA for permit applications, as needed
- confirmation of sampling protocols
- coordination with analytical laboratories
- preparation of field documents that may be required by FORA or the City such as Health and Safety Plans, Traffic Control Plans, Hazardous Materials Plan, and/or Noise Control Plans.

Logistics for the proposed field construction program would include any mitigation measures that may be required by the EIR.

#### 5.1.1. Permits

The numerous permits required for the Proposed Project are documented in the EIR. The primary permits related to well drilling and construction are listed below.

##### 5.1.1.1. Fort Ord Reuse Authority (FORA) Right-of-Entry

Until the ESCA parcels have been cleared by FORA (scheduled for 2015), a Right-of-Entry (ROE) permit will be required for any field work conducted in the Proposed Project Injection Well Facilities area. MRWPCA would be required to submit a workplan for proposed field activities and an ROE application with a reimbursement agreement for application review. For the recently-completed MRWPCA field program, this ROE permit process was initiated in March 2013, but not completed until September 2014 (18 months later). Although there are some efficiencies that have been learned during this initial application phase, long lead times would still be required for FORA ROEs for the proposed field construction program.

#### 5.1.1.2. City of Seaside Conditional Use Permit and Encroachment Permit

The City of Seaside has established operating procedures for any projects involving soil disturbance or groundwater wells within the former Fort Ord lands (Chapter 15.34, Seaside Municipal Code, also referred to as the Ordnance Ordinance). Permit conditions are applicable to projects that disturb greater than 10 cubic yards ($yds^3$) of soil on certain parcels identified as having munitions or explosives of concern or a project involving a well installation or groundwater replenishment (limited to parcels having a groundwater covenant as defined by the ordinance that restricts groundwater use).

The Proposed Project Injection Well Facilities would be located on portions of two parcels (APN 031-151-048-000 and APN 031-211-001-000) that are not associated with a groundwater covenant in the Ordnance Ordinance but are associated with some construction restrictions. These include no soil disturbance without a soils management plan, notification of possible MEC, and access requirements.

The City will also require a Conditional Use Permit (CUP) to be approved by the Planning Commission. Currently, the City views the wells associated with the Proposed Project as a utility that requires a CUP application and fee.

#### 5.1.1.3. Monterey County

Monterey County Drinking Water Protection Services, Environmental Health Bureau requires a permit for all water supply and monitoring wells. Application forms can be downloaded from the Environmental Health Bureau website for the monitoring wells. For the proposed injection wells, the Drinking Water Protection Services should be contacted directly. The applications must be signed by the property owner; for this project, an encroachment permit from a municipality (e.g., City of Seaside) can be submitted in lieu of a property owner signature. For the recent monitoring well, a signature from FORA was also required because they were the land owner at that time. Application fees are required for each well.

#### 5.1.1.4. California Department of Water Resources (CDWR) and Monterey County Water Resources Agency (MCWRA)

All wells drilled in California, including monitoring and injection wells, require a permit from the CDWR. Such permits, including required completion of a Driller's Log, would be secured by the drilling contractors used for Proposed Project. In Monterey County, MCWRA has a cooperative agreement with the CDWR to manage the Driller's Log permits. Also, DEH provides paperwork from the Monterey County DEH well construction permit process (described above) to MCWRA.

#### 5.1.1.5. CRWQCB and SWRCB Division of Drinking Water

Currently, groundwater replenishment projects must obtain a permit from the CRWQCB (Waste Discharge Requirements and/or Waste Discharge and Water Reclamation Requirements) in accordance with California Water Code Sections 13523 and 13523.1. This process entails submittal of a Report of Waste Discharge to the CRWQCB and an Engineering Report for review by the CRWQCB and approval by the SWRCB Division of Drinking Water. The Division of Drinking Water issues a conditional approval letter, which contains provisions for the CRWQCB to include in the permit. Effective July 1, 2014, California Water Code Section 13528.5 provides the SWRCB (and hence the Division of Drinking Water) with the authority to issue groundwater replenishment permits. At this time is it is not known if or when the Division of Drinking Water might take over the permitting responsibility from the CRWQCB.

An additional permit for well construction may also be required by the CRWQCB. If drilling methods result in application to land of cuttings or drilling fluids/development water, a Notice of Intent may be required to comply with a state-wide General Order (No. 2003-0003-DWQ). This General Order allows the CRWQCB to grant a permit through an administrative approval process for *General Waste Discharge Requirements for Discharges to Land with a Low Threat to Water Quality*. General Order No. 203-0003-DWQ applies to well development discharge, monitoring well purge water discharge, and boring waste discharge.

#### 5.1.1.6. U. S. Environmental Protection Agency (USEPA) Injection Well Registration

The USEPA administers the Underground Injection Control (UIC) Program, which contains requirements for various classes of injection wells in the state. Injection wells associated with the Proposed Project are designated as Class V wells under the UIC program. Any injection project planned in California must meet the State Sources of Drinking Water Policy, which ensures protection of groundwater quality for drinking water supplies, and therefore a USEPA permit would not be necessary. However, the wells must be registered on the UIC injection well database maintained by USEPA.

### 5.1.2. Well Technical Specifications

Technical Specifications would be developed for each of the Proposed Project injection wells and monitoring wells. These detailed documents would provide a preliminary well design and describe methods and standards for each well. The specifications would also identify requirements for drilling cuttings and fluid disposal, and use of local utilities, if allowed. In addition, specifications would provide constraints associated with the ROE or other permits not obtained by the drilling contractor. The documents would require preparation and implementation of a site-specific health and safety program.

## 5.2. INSTALLATION AND TESTING OF DEEP INJECTION WELLS

The drilling of a deep injection well would require sufficient space for drilling rig access and for storage of temporary wastes such as drilling fluid and cuttings from the borehole. In general, a relatively small site (smaller than about 100 feet by 100 feet) can be accommodated, but may result in increased well costs if staging and equipment storage is limited or if onsite equipment cannot be located for optimal construction operations. However, such a site may not be sufficient to support additional project components such as pits or holding tanks for well discharge. Technical specifications would be based on the drilling site available.

### 5.2.1. Drilling

The proposed deep injection wells would be drilled with rotary drilling methods similar to those employed for the ASR wellfield. Those wells were drilled using reverse rotary drilling methods and polymer-based drilling fluids to minimize deep invasion of fluids into the formation. Similar methods would be used for the Proposed Project wells to minimize borehole impacts from drilling fluids. Cuttings from the borehole would be logged by a California Certified Hydrogeologist. Open-hole geophysical logging would also be conducted.

It is anticipated that at least one of the Proposed Project monitoring wells would be installed prior to the installation of the proposed deep injection well. This would provide site-specific information and inform details of injection well design. The well would also provide a monitoring point during injection well testing.

### 5.2.2. Design, Installation, and Development

The proposed deep injection well design would incorporate 18-inch to 24-inch diameter production casing and a wire-wrap stainless steel screen. Screen selection and filter pack design would be developed using both cuttings from the adjacent proposed monitoring well in addition to data collected from nearby ASR wells. Mechanical and pumping techniques would be used to develop the well after installation. Video logs would be conducted in the final wellbore to document well construction and ensure appropriate down-hole conditions for equipping.

### 5.2.3. Testing and Equipping

Both variable (step) and constant discharge pumping test and constant injection tests would be completed in the proposed injection wells. An 8- to 24-hour test length would be sufficient for the variable and constant rate tests. Flowmeter surveys would be conducted following pumping and injection testing to identify water movement within the wellbore. For planning purposes, it is assumed that both static and dynamic flow testing will be conducted.

The variable and constant rate discharge tests would be conducted immediately following installation and well development and would provide aquifer parameters to support final well design. Injection testing could be conducted after the constant rate discharge tests, but would require product water that may not be available at the time of well construction. As such, injection testing may be delayed unless an adequate alternative water source is available for testing purposes.

At the end of the constant rate discharge test, a water quality sample would be collected to confirm local groundwater quality. Constituents targeted for analysis would be based on compliance with the SWRCB and CRWQCB requirements. The well would be disinfected with chlorine to control any bacterial growth introduced during installation.

A 400 horsepower, variable speed pump for the proposed injection wells is assumed for planning purposes and costs. Additional requirements for wellhead equipment and surface connections are being developed with others on the Proposed Project team.

To maintain injection capacity, the wells would need to be taken offline for periodic pumping to back-flush the well screens and repair or prevent physical clogging. Details for the back-flush basin were discussed previously in this report (Section 4.3). This water would not be lost from the project, but would be allowed to percolate back into the groundwater basin.

## 5.3. INSTALLATION AND TESTING OF VADOSE ZONE WELLS

The drilling, installation, and testing of the proposed vadose zone wells would likely require less surface area than the proposed deep injection wells. Currently, the proposed vadose zone wells are planned to be on the same well sites as the proposed deep injection wells to minimize construction and ground disturbance to a smaller area than would otherwise be needed.

### 5.3.1. Drilling

The proposed vadose zone wells would be drilled using the bucket auger drilling method. The field data and results from the drilling, logging, and installation of GWR MW-1 and DIW-1 would be used to confirm the depth and placement of well screens. Grab samples in the vadose zone well boreholes would be logged by a certified California Hydrogeologist during drilling to assist in final vadose zone well design. Open-hole geophysical logging (including induction logging and other logs suitable for the unsaturated zone) would be conducted to assist in stratigraphic characterization. The final logging program would depend on the quality of the data collected in DIW-1. The usefulness of additional logging, such as a video log, would be evaluated based on results of the initial field investigation and pilot testing.

### 5.3.2. Design and Installation

The preliminary vadose zone well design is discussed in Section 4.2.4 and shown on Figure 12. An 18-inch diameter casing would be set in a borehole drilled to below 200 feet. The annular space would be filled with a high quality gravel pack appropriately sized to avoid plugging the formation with filter-pack fines during long-term injection. Dry chlorine would be mixed with the gravel pack during installation to control bacterial growth that may have been introduced during well installation. Air vents and a transducer tube would also be installed in the annular space of the well.

The casing would be perforated over an approximate 100-foot interval to optimize the open area for recycled water recharge. An eductor tube (typical 4-inch diameter) would be installed in the casing and used to introduce water into the wellbore in a manner that avoids turbulent flow in the open casing and potential air entrainment. The eductor tube would be installed with an orifice plate on the bottom or a variable orifice valve to introduce specified sustained or variable flows. An air vent would also be installed in the casing to allow air to escape while being displaced by the water.

### 5.3.3. Pilot Testing and Monitoring

Injection testing would be conducted to establish a wetting front and estimate long-term injection rates. A one-month test is assumed to be sufficient to inform any well design modifications for the remaining wells. In general, the subsequent three vadose zone wells would be installed in the same manner as the first vadose zone well, which is considered a pilot well.

To allow for monitoring during pilot testing, a small-diameter boring would be drilled adjacent to the pilot vadose zone well to install temperature probes or other monitoring devices to track the wetting front of the project water as it percolates through the vadose zone. This monitoring would provide valuable information for the demonstration of underground retention time associated with the SWRCB Regulations (SWRCB, 2014).

Hook-up to the conveyance system may incorporate a butterfly valve that allows automatic recharge operation at each well. All wells would be equipped with a high water level alarm. Well hook-ups and onsite water supply lines would be coordinated with pipeline and surface equipment designs by others. Once installed, the vadose zone wells would require a relatively small surficial footprint and can be incorporated into the Proposed Project close to deep injection wells.

## 5.4. Drilling, Installation and Development of Monitoring Wells

The Proposed Project monitoring wells would be drilled with the direct or reverse rotary method. Wells would either be installed as well clusters (separate casings in two smaller boreholes) or nested wells (two casings in one larger borehole) in order to monitor both the Paso Robles and Santa Margarita Aquifers at each monitoring well location. For planning purposes, well clusters are assumed.

Geologic samples from all boreholes would be logged by a California Certified Hydrogeologist. Geophysical logging would be conducted to supplement geologic data from the well cuttings.

Casing diameter would need to be sized to accommodate a sampling pump sufficiently large to lift a groundwater sample from depths greater than 400 feet (minimum 3-inch outer diameter). Wells would be drilled to similar depths as the closest proposed deep injection well and screened similar to injection wells for the Santa Margarita Aquifer. For the Paso Robles Aquifer monitoring, well casings would be screened across the upper-most permeable zones and close to the water table in order to track shallow recharge from the proposed vadose zone wells.

## 5.5. GROUNDWATER MONITORING PROGRAM

Following installation, all of the Proposed Project monitoring wells and deep injection wells would be sampled and analyzed to collect baseline water quality data in conformance with SWRCB Division of Drinking Water and CRWQCB requirements.

# 6. PROPOSED PROJECT INJECTION WELL FACILITIES: SEQUENCING AND SCHEDULE

Field planning for the Proposed Project Injection Well Facilities would begin soon after certification of the Final EIR. One of the initial steps in field planning would involve the preparation of Technical Specifications for the wells and applications for drilling permits. The FORA right-of-entry permit for the recently installed monitoring well took approximately 14 months to secure.

The field activity sequencing could consider some alternate scheduling to minimize construction time while providing some flexibility for unanticipated subsurface conditions that would impact well drilling.  A list of steps describing the potential sequencing of the Proposed Project well program is provided below. Well locations are shown on Figure 10. The field program generally begins in the north (DIW-1) and ends in the south (DIW-4).

1. Mobilize a bucket auger rig to the field to install surface conductor casing at the two northern monitoring well sites (GWR MW-1 and GWR MW-2). Then move the auger rig to each of the four deep injection well sites (DIW-1, DIW-2, DIW-3, and DIW-4 for conductor casing installation. Surface casings may also be installed for GWR MW-3 and MW-4 before the bucket auger rig is released. Each surface casing is assumed to be installed in one day including rig mobilization.

2. As soon as the bucket auger rig completes the casing at GWR MW-1, mobilize a reverse rotary drilling rig to the field to drill, log, install, and develop two well clusters (Shallow and Deep) at the first monitoring well location. Data from GWR MW-1 would be used to finalize the pre-drilling design of DIW-1. The reverse rig can then be moved to GWR MW-2 to complete the monitoring wells on the north end of the site. Monitoring wells would need to be the first wells installed to allow for collection of baseline groundwater data prior to project startup. A small pump rig can be moved onto GWR MW-2 to complete the monitoring wells while the reverse rotary rig is moved to DIW-1.

3. The reverse rotary rig would drill and install DIW-1. The pump rig would be brought onto DIW-1 for well development and pumping/injection testing, allowing the reverse rig to move to DIW-2. Pumping test would be conducted initially with the pump rig. The injection testing may be delayed, depending on the availability of source water; product water would not be available initially after well completion. The remaining DIW wells would be drilled in a similar manner with the pump rig following the reverse rig.

4. Monitoring well clusters at GWR MW-3 and MW-4 can be completed with the reverse rotary rig after completion of the deep injection wells. Alternatively, an additional reverse rotary rig could be brought in to complete the monitoring well program prior to drilling DIW-4. In that way, hydrogeologic data in the southern

Proposed Project area could be obtained that might inform well design modifications for DIW-4. In addition, baseline sampling events would need to be conducted prior to injection into DIW-4.

5. Mobilize a bucket auger rig to the field to drill a pilot vadose zone well, VZW-1. The vadose zone program could begin after the installation of DIW-1 or after all deep injection wells and monitoring wells are installed. It is recommended that at least the two northern monitoring wells and DIW-1 be completed prior to construction of vadose zone wells. This would allow analysis of the site-specific hydrogeologic data collected during the drilling of the three wells to ensure an optimal pre-drilling design of the vadose zone wells. The first vadose zone well should be viewed as a pilot well or test well to allow testing of the injection capacity prior to installation of the remaining wells. The injection capacity of 500 gpm/well used in project planning is highly conservative, given the thick and permeable sands in the vadose zone. In addition, the maximum amount of injection into the Paso Robles Aquifer is small (277 gpm) and may be accommodated with fewer wells. However, this testing and sequencing of wells would allow optimization and modification of vadose zone well design, as necessary.

6. An additional, small-diameter boring would be installed adjacent to the pilot vadose zone well and equipped with temperature probes or other vadose zone monitoring devices to allow tracking of the wetting front with the initial pilot well testing. The boring could be installed in close proximity to the vadose zone well and would not require additional construction space than has already been allocated for the EIR evaluation. A 30-day (approximate) pilot test would be conducted in VZW-1 to quantify the injection capacity of the vadose zone at that location and to inform future well design.

7. Construction and installation of the back-flush basin could be conducted during the initial drilling of DIW-1 to provide a temporary location for well testing water. Alternatively, other arrangements could be made for testing water, allowing the back-flush basin construction to be completed during conveyance piping and wellhead equipping. It is assumed that pipeline installation would be best conducted soon after the drilling program has been completed to allow for injection testing.

Depending on the timing of other activities, the field program could also be completed in phases. For example, GWR MW-1, MW-2, DIW-1 and DIW-2 could be completed in an initial phase to allow for tracer testing and groundwater modeling prior to installation of the remaining program wells. Phasing would be controlled by the amount and timing of product water available for injection.

# 7. GROUNDWATER IMPACTS ASSESSMENT

The Seaside Groundwater Basin is an important resource for a reliable water supply for the Monterey Bay area. Increased replenishment of basin aquifers has many benefits including locally higher groundwater levels and increased basin yield, while mitigating the effects of over-pumping during the dry season. Potential impacts from the Proposed Project on water levels, quantity, and quality are described in this section.

## 7.1. GROUNDWATER LEVELS AND QUANTITY

In order to predict the transport of recycled water in the groundwater system and to evaluate potential impacts of the Proposed Project on groundwater levels and quantity, HydroMetrics has conducted groundwater modeling using the Seaside Basin groundwater flow model. The modeling of the Proposed Project builds on previous modeling runs that were used during project development to allocate project water between the two basin aquifers (HydroMetrics, October 2013). The initial project development modeling was described previously in this report (Section 3.3.5.1); the TM documenting the project development modeling results is included in this report as Appendix B. The Proposed Project modeling is included in this report as Appendix C.

The Proposed Project modeling incorporated the proposed delivery schedule and drought reserve account as described in Section 2. The appropriate delivery schedule of the eight schedules shown on Table 1 was assigned to each year of project operation in the modeling based on hydrology and the balance of the drought reserve account. The amounts used for injection for each year of the 25-year simulation are documented in an attachment at the end of the HydroMetrics TM (Appendix C).

A brief summary of the Proposed Project modeling in Appendix C and implications for project impacts on groundwater resources are discussed in the following sections.

### 7.1.1. Modeling Approach

The Proposed Project modeling was conducted using the predictive model setup that the Watermaster has developed previously for analyzing future conditions in the basin. The predictive model covers a 33-year period from 2009 through 2041. The Proposed Project well operations are currently anticipated to begin in 2017. For purposes of the modeling analysis, the injection was simulated as beginning in October 2016 to cover the entire Water Year (WY) 2017 and allow for a 25-year analysis of the project.

The Proposed Project modeling was also conducted using reasonable assumptions of future operation of production wells in the basin. Production wells were assumed to be pumping in the model based on court-allocated pumping and agreements associated with the Seaside Basin adjudication. CalAm production wells (and the ASR wells) were assumed to be the recovery (extraction) wells for the Proposed Project product water based on existing well capacity and water demand (see Appendix C).

The Proposed Project modeling also incorporated a quantitative assessment of future operations of the ASR Project. This assessment was developed by MPWMD, which coordinates the ASR injection and extraction operations under cooperative agreements with CalAm. The assessment was based on historical hydrologic conditions on the Carmel River between 1987 and 2008 and approved rules of ASR operation. This allowed MPWMD to predict both injection and recovery schedules at each ASR well over time. By incorporating this assessment into the model setup, the Proposed Project was evaluated during a full range of ASR injection and recovery (pumping) conditions (see Appendix C).

#### 7.1.2. Modeling Results

The Proposed Project modeling simulated the travel time between injection wells and the closest production wells under the varying hydrologic and pumping conditions throughout the 33-year simulation, incorporating all of the associated delivery schedules in Table 1. The Proposed Project modeling also evaluated changes in water levels at eight production wells over time and assessed the potential for the Proposed Project to potentially affect the risk for seawater intrusion. Full modeling results are presented in Appendix C and summarized below.

##### 7.1.2.1. Flow Paths and Travel Time to Production Wells

The travel time analysis, a modeling process referred to as particle tracking, evaluated the transport of recycled water from injection well to production (extraction) wells. The analysis allows the visualization of groundwater flow paths and provides details for demonstrating compliance with the underground retention time requirements in the SWRCB Regulations.

For the particle tracking analysis, “particles” (acting as a simulated tracer of the recharged water) were released at each of the eight proposed injection well sites (four deep injection wells and four vadose zone wells) in every month of the 25-year simulation when the Proposed Project was in operation. This ensured that the fastest travel time under numerous combinations of pumping and ASR operations could be identified. Particles were simulated as being released around the edges of each model cell containing an injection well and tracked as the water flows downgradient in the groundwater system. Particles were tracked until they reached a cell containing a production well. Tracking from the edges of cells (rather than at the well within the cell) allows for a thorough examination of particle transport, but is also conservative in that it eliminates the additional distance a particle would travel between the actual well and the edge of a cell.

The fastest flow paths as indicated by the model particle tracking simulations are shown on Figure 13. The upper map on Figure 13 shows simulated flow paths from the deep injection wells and the lower map shows the paths from the vadose zone wells. Simulated flow paths from the deep injection wells are being influenced by the dynamic system created by changes in pumping and injection in both production and ASR wells. As shown, the shortest simulated flow paths are from DIW-3 to the nearby ASR wells (shown in red on the top of Figure 13). Simulated vadose zone flow paths are not impacted by the ASR wells, which are screened in the deeper Santa Margarita Aquifer. Recycled water injected in the vadose zone wells flows downgradient unimpeded until arrival at wells that are at least partially screened in the Paso Robles Aquifer (e.g., Paralta, Luzern). Injection at VZW-1 does not arrive at any production well during the travel time simulation shown in Figure 13, but provides replenishment to the local Paso Robles Aquifer as water flows downgradient.

The fastest travel times for each of the injection wells are tabulated by HydroMetrics (Appendix C) and reproduced in Table 10. The shading for each injection well in Table 10 generally corresponds to the colors of the respective well flow paths on Figure 13.

**Table 10. Simulated Fastest Travel Times between Injection and Extraction Wells, in days**

| Extraction Well | Well of Origin of Particles with Fastest Travel Time (Days) | | | | | | | |
|---|---|---|---|---|---|---|---|---|
| | DIW-1 | DIW-2 | DIW-3 | DIW-4 | VZW-1 | VZW-2 | VZW-3 | VZW-4 |
| ASR 1&2 | - | 371 | 327 | 1,780 | - | - | - | - |
| ASR 3&4 | 724 | - | - | 3,074 | - | - | - | - |
| Luzern | - | - | - | - | - | - | 3,140 | - |
| Ord Grove | 3,718 | 1,952 | 1,052 | 1,497 | - | - | - | 4,250 |
| Paralta | 506 | 521 | 852 | 2,076 | - | 5,114 | - | - |

Note: - = no particle traveling between wells

As shown in Table 10, simulated travel times vary considerably from each injection point to a production well. The deep injection wells provide water to six different wells (including four ASR wells, Paralta, and Ord Grove), varying from 327 days (about 11 months) to more than 3,000 days (more than eight years). Simulated travel times are longer for the injection into the vadose zone wells, but water is still being added to basin storage, which increases hydraulic gradients and groundwater flow toward downgradient wells.

Regarding the underground retention time in the SWRCB Regulations, it appears that project water would remain in the groundwater system for at least six months, which would provide the Proposed Project with the maximum allowed 6-log virus removal credit. However, the demonstration of retention time with groundwater modeling requires a one-year travel time for approval of the six-month credit; DIW-3 does not meet the one-year requirement for all conditions (including the fastest simulated travel time for DIW-3 shown in Table 10). Although the simulated travel times from all injection wells meet the one-year requirement during 20 of the 25-year GWR simulation period, simulated travel times for injection in DIW-3 during five years of the simulation are between 327 days and 365 days. The shortest simulated travel time from DIW-3 to ASR-1/ASR-2 is 327 days, 38 days short of the 365-day simulated travel time needed for the maximum 6-log removal credit. The modeling does, however, support at least a 5-log removal credit. The six-month credit would be re-evaluated as part of the tracer testing to be conducted after the Proposed Project begins operation.

#### 7.1.2.2. Groundwater Levels

Because the Proposed Project would provide additional water for downgradient extraction, the project would result in both higher and lower water levels in existing basin wells over time depending on the timing of extraction and the buildup of storage in the basin. An examination of eight key production wells was completed by HydroMetrics and presented for the entire 33-year simulation period (including 25 years of GWR project operation) (HydroMetrics, January 2015, in Appendix C). These hydrographs illustrate simulated changes in water levels over time at various locations within the basin with and without the Proposed Project. Hydrographs for all eight wells (with one hydrograph representing both ASR-1 and ASR-2) are presented and discussed in the HydroMetrics TM (see Appendix C). Four example hydrographs comparing the *Proposed Project* with a *No Project* scenario are presented on Figures 14 and 15, representing deep and shallow water levels, respectively.

##### *7.1.2.2.1. Deep Water Levels*

Figure 14 presents water levels representing two ASR wells closest to the Proposed Project Injection Well Facilities (ASR-1 and ASR-2) and a downgradient production well, Ord Grove 2. Well locations are shown on Figure 10 (Ord Grove 2 is labeled Ord Grove on the figure). On both Figures 14 and 15, the *No Project* scenario is represented by the blue line and the GWR *Project* scenario is represented by the green line. The Proposed Project is simulated to begin in late 2016 (WY 2017); prior to that time period, the water levels for the *No Project* and *Project* scenarios are the same (Figures 14 and 15).

In general, simulated deep water levels (Figure 14) rise in the ASR and Ord Grove wells soon after the Proposed Project is implemented in late 2016. Although simulated water levels continue to rise and fall due to seasonal fluctuation associated with water demand and pumping, water levels do not fall to the lower levels observed in 2011 – 2016. The general rise in water levels occurs under both *Project* and *No Project* conditions. This change is primarily due to the decrease in overall basin pumping as required under the adjudication. For the ASR wells, simulated water levels under the *Proposed Project* scenario are similar to or slightly higher than the *No Project* water levels.

An exception to this occurs during a drought cycle, generally represented by the time period 2031 – 2035, when simulated water levels associated with the Proposed Project are one to nine feet lower than under *No Project* conditions. During that time, the ASR wells are pumping to recover GWR Project water under *Project* conditions, but the ASR wells are not operating under *No Project* conditions. ASR wells are idle during *No Project* conditions because, during drought conditions, no water is available to be extracted from the Carmel River Alluvial Aquifer for ASR injection and no stored water is available for ASR recovery. Because the simulated pumping for the *Project* conditions causes water levels in the wells to fluctuate more than for the *No Project* conditions, simulated water levels are lower on a seasonal basis under the *Project* conditions during a simulated drought cycle. This impact is seen as beneficial overall in that simulated water levels are not lowered significantly and only for a short duration, while simulated groundwater pumping and water supply has been increased during a drought. Under both scenarios, overall simulated water levels remain higher than current levels.

For the Ord Grove well (Figure 14), simulated water levels are relatively similar for the *Project* and *No Project* scenarios from project implementation to about 2029. At that time, *Proposed Project* simulated water levels are generally lower (up to about 10 feet lower), but typically less than about five feet lower during the bottom of each pumping cycle. Again, this is due to the increased pumping allowed by the increased recharge of the Proposed Project. Also, the simulated lower water levels during the drought cycle are higher than the low levels reached prior to the initiation of the Proposed Project. Because simulated water levels are higher than current levels while production is being increased in the basin, the Proposed Project is considered to have a beneficial impact on water supply without a significant adverse impact to groundwater levels and wells.

##### *7.1.2.2.2. Shallow Water Levels*

Figure 15 documents changes in simulated water levels under both *Project* and *No Project* scenarios, as illustrated by the Luzern and PCA-W Shallow wells (both screened in the Paso Robles Aquifer). Similar to the deeper hydrographs, simulated water levels generally rise under both *Project* and *No Project* conditions due to an overall decrease in basin pumping. After the Proposed Project is initiated, the Luzern well is pumped to recover the recharged water, although the water has not yet arrived in the vicinity of the well. This creates slightly lower simulated water levels (up to about seven feet) in early stages of the Proposed Project. This also occurs in the PCA-W Shallow well, but the difference is only a few feet because this well is not being pumped to recover Project water. With time, simulated water levels in the Luzern and PCA-W wells rise under the *Project* scenario as Project recharge water moves downgradient toward these wells. The benefit of additional recharge is demonstrated by higher simulated water levels associated with the Proposed Project during drought conditions for both of these wells (beginning in about 2030).

Importantly, simulated water levels do not fall below pre-project levels and do not fall below the Protective Elevation for seawater intrusion (see the Protective Elevation line on PCA-W Shallow well on Figure 15). These Protective Elevations have been determined by the Seaside Basin Watermaster to provide target water levels that are considered to protect the basin from the adverse consequences of seawater intrusion (HydroMetrics, 2009). Although other coastal wells remain below Protective Elevations with and without the Proposed Project, the changes predicted to be associated with the Proposed Project are demonstrated by the hydrograph of PCA-W Shallow, the closest coastal well. These data indicate that the Proposed Project will not exacerbate the risk for seawater intrusion compared to the *No Project* conditions.

#### 7.1.2.3. Groundwater Quantity

The modeling simulations of the Proposed Project recover only the water recharged to the aquifers. As such, the Proposed Project would not result in a significant change in groundwater storage in the basin because the water being injected would eventually be extracted for municipal use. Further, the Proposed Project would increase basin yield and groundwater supply.

## 7.2. IMPACTS ASSESSMENT ON GROUNDWATER LEVELS AND QUANTITY

Based on the results of the modeling and groundwater analyses, potential impacts of the Proposed Project on groundwater levels and quantity are compared to thresholds of significance as developed from CEQA guidance.

### 7.2.1. Thresholds of Significance

Appendix G of the 2013 CEQA Guidelines provides the following question to be addressed as part of the Proposed Project EIR regarding groundwater resources:

> *Would the Proposed Project substantially deplete groundwater supplies or interfere substantially with groundwater recharge such that there would be a net deficit in aquifer volume or a lowering of the local groundwater table level (e.g., the production rate of pre-existing nearby wells would drop to a level which would not support existing land uses or planned uses for which permits have been granted)?*

The criterion above was applied to the results of the groundwater modeling as summarized in the following section. Additional CEQA questions and significance criteria have been developed for addressing water quality. The analysis of groundwater quality is provided in Section 7.3 with the impacts analysis and the significance criteria provided in Section 7.4.

### 7.2.2. Analysis of Potential Impacts

As discussed above, simulated water levels are sometimes lower under the *Project* scenario because of increased pumping at existing extraction wells. However, simulated water levels are lowered only about 10 feet or less and would be lowered for a relatively short duration, typically for a few months. In addition, simulated water levels are generally higher than pre-project levels. As such, none of the municipal or private production wells would experience a reduction in well yield or physical damage. All existing wells would be capable of pumping the current level of production or up to the permitted production rights.

In addition, analysis of the closest shallow coastal well (PCA-West Shallow) indicates that increased pumping of project water would not result in water levels falling below elevations protective of seawater intrusion. Although it would take time for the beneficial impacts of recharge to reach coastal pumping wells, the increased pumping of nearby Paso Robles production wells would only reduce water levels about two feet near the coast. The closest coastal well, PCA-W shallow remains above Protective Elevations for the duration of the model simulation period.

In addition, there would be no adverse impacts to the quantity of groundwater resources. Because the Proposed Project would only recover the amount of water injected, there would be no long-term change in groundwater storage associated with the Proposed Project.

## 7.3. EXISTING GROUNDWATER QUALITY AND PROPOSED PROJECT RECYCLED WATER QUALITY

In order to evaluate potential impacts on water quality from the Proposed Project, both ambient groundwater quality and quality of the Proposed Project recycled water are characterized. The characterization of ambient groundwater quality establishes a baseline for a water quality impacts assessment in support of the EIR. The characterization incorporates available data and previous investigations, and also summarizes the results of new geochemical evaluations regarding the interaction of the existing geologic sediments in the Proposed Project area with product water generated from the GWR pilot/demonstration treatment facility[8]. Those geochemical analyses are presented more fully in a separate report on the MRWPCA field program (Todd Groundwater, February 2015).

The Proposed Project Injection Well Facilities study area shown on Figure 2 was used as the focus of the groundwater quality characterization. In order to incorporate additional available water quality data, the study area was expanded about 2,000 feet to the west to include five additional production wells. Water quality data were also evaluated for: 1) the Carmel River water, which is injected into nearby ASR wells; and 2) predicted recycled water quality to be produced at the AWTF and to be injected into the Seaside Basin. The geochemical evaluation utilized data from the advanced treatment pilot testing and bench scale chemical stabilization, which did not include all of the new source waters to be treated at the RTP and subsequently treated at the proposed AWTF. However, the data are a reasonable representation for purposes of the EIR. Types of data and analyses are described in the subsequent sections of this report.

### 7.3.1. Data Sources

Previous investigations on groundwater quality in the Seaside Groundwater Basin were reviewed including Fugro (1998), Yates et al. (2005), and HydroMetrics (2009). Recent annual reports developed by the Watermaster contain evaluations of potential seawater intrusion (HydroMetrics, 2013). Information was also reviewed in the Final Salt and Nutrient Management Plan (SNMP), which includes summaries of ambient groundwater quality including concentrations of TDS, nitrate, and other constituents (HydroMetrics, 2014).

Recent and historical groundwater quality data for the Proposed Project Injection Well Facilities study area were provided by MPWMD and CalAm. These data were supplemented with recent data collected by Todd Groundwater in association with the MRWPCA field program. Data provided from these sources are summarized in Table 11 and described in the following sections.

---

[8] A description of the water quality of the Proposed Project product water is provided in Section 7.3.4. based on a bench-scale stabilized sample from the pilot treatment facility.

**Table 11. Source of Groundwater Quality Data**

| Water Quality Database | Data Source | | |
|---|---|---|---|
| | MPWMD | Cal-Am | MRWPCA |
| *# Wells* | 14 | 8 | 6 |
| *Time Period* | 1990-2012 | 2010 - 2013 | 2014 |
| Anions | x | x | x |
| Metals (including major cations) | x | x | x |
| Conventional Chemistry Parameters | x | x | x |
| Chlorinated Pesticides and PCBs | x | x | x |
| Nitrogen and Phosphorus Pesticides | x | x | x |
| Organic Analytes | x | x | x |
| Chlorinated Acids | x | x | x |
| Carbamates | | x | x |
| Volatile Organic Compounds (VOCs) | x | x | x |
| Semivolatile Organic Compounds | | x | x |
| Haloacetic Acids | | x | x |
| Herbicides | | x | x |
| Nitroaromatics and Nitramines (Explosives) | | | x |
| Other (e.g., isotopes) | | | x |

*PCBs – Polychlorinated Biphenyls*
*Organic Analytes – including 1,2-Dibromo-3-chloropropane, 1,2-Dibromoethane (EDB), diquat, endothall, glyphosate*
*Carbamates – organic compounds derived from carbamic acids*

#### 7.3.1.1. MPWMD Groundwater Quality Monitoring Program

MPWMD conducts a basin-wide groundwater monitoring program with support from the Seaside Basin Watermaster. Components of the program also serve as the monitoring program for the ASR Project. An electronic database in Access© format was provided by MPWMD for this analysis. The database included the Watermaster monitoring program data along with historical groundwater quality data dating back to 1990. Data from 14 wells were used in the water quality characterization.

#### 7.3.1.2. CalAm Production Well Monitoring

CalAm monitors the water quality from their production wells in the basin in compliance with drinking water requirements per California Water Code, Title 22. These data were provided to Todd Groundwater in Excel© format for eight production wells in the water quality study area and included samples from 2010 through 2013.

#### 7.3.1.3. Water Quality Analyses from MRWPCA Field Program

From December 2013 through February 2014, Todd Groundwater conducted a field program for MRWPCA in support of the Proposed Project. The program included a detailed vadose zone analysis, installation and sampling of a new monitoring well (MRWPCA MW-1), and groundwater sampling from five additional wells in the Proposed Project Injection Well Facilities area including two upgradient monitoring wells (FO-7 Shallow and FO-7 Deep) that had not previously been sampled for groundwater quality. The field program, including all testing and analyses, is documented in a separate report (Todd Groundwater, February 2015). Groundwater sampling results were incorporated into this report to support the water quality impacts assessment. Wells sampled during the field program are summarized in Table 12.

**Table 12. Wells Sampled in 2013-2014 Proposed Project Field Program**

| Well | Well Type | Screened Aquifer | Well Depth (feet, bgs) | Screen Interval (feet, bgs) |
|---|---|---|---|---|
| **MRWPCA MW-1** | Monitoring | Paso Robles | 521 | 421 - 446; 466 - 516 |
| **FO-7 Shallow** | Monitoring | Paso Robles | 650 | 600 - 640 |
| **FO-7 Deep** | Monitoring | Santa Margarita | 850 | 800 - 840 |
| **PRTIW** | Irrigation | Paso Robles | 460 | 345 - 445 |
| **ASR MW-1** | Monitoring | Santa Margarita | 740 | 480 - 590; 610 - 700 |
| **Seaside Muni 4** | Production | Santa Margarita | 560 | 330 - 350; 380 - 420; 430 - 470; 490 - 550 |

*Notes: All wells sampled January/February 2014. bgs = below ground surface.*

An expanded list of constituents was analyzed in these samples (compared to the list of constituents available from monitoring at other basin wells) including:

- chemicals including explosives associated with former Fort Ord activities
- constituents in the SWRCB Regulations
- constituents of emerging concern (CECs) as included in the SWRCB Recycled Water Policy
- isotopic data to support hydrogeologic analysis
- data to support geochemical modeling in order to analyze the compatibility of the Proposed Project recycled water with ambient groundwater.

Laboratory analyses of groundwater samples collected at these six wells are presented in Appendix D (as Tables D-1A through D-1P).

#### 7.3.1.4. Water Quality Database

Data sets from the sources described above were compiled into an Access© database. This database was used to characterize groundwater quality and identify potential constituents of concern for the Proposed Project water quality impacts assessment.

### 7.3.2. Groundwater Quality Characterization

The available data representing general groundwater chemistry were checked for accuracy and then evaluated using various geochemical techniques, as summarized in this section.

#### *7.3.2.1.* Geochemical Analysis and Methodology

Major cation (calcium, magnesium, sodium, potassium) and anion (chloride, sulfate, bicarbonate and carbonate) analyses were plotted on standard Stiff, Trilinear (Piper), Schoeller diagrams (see Hem, 1989), and Brine Differentiation (BDP) plots. Analyses reported in milligrams per liter (mg/L) were recalculated to milliequivalents per liter (meq/L) to evaluate water chemistry and possible sources of groundwater recharge. In the absence of total bicarbonate data, reported total calcium carbonate ($CaCO_3$) concentrations were recalculated to bicarbonate ($HCO_3^-$) using a conversion factor from Hounslow (1995). To validate the general mineral data, a cation-anion balance error analysis was conducted using the groundwater data.

For geochemical plotting purposes, the most recent available data were used for wells near the Proposed Project Injection Well Facilities. The six wells included in the MRWPCA field program contained the most recent sampling (January or February 2014). Data from July 2012 through November 2013 were used for all other wells except the Ord Terrace well, which contained a more complete data set from September 2009.

#### 7.3.2.2. Analytical Accuracy Using Charge Balance and Cation/Anion Ratios

A cation-anion balance (also known as a charge balance) was calculated for the available analytical data. This is a method by which water quality analytical accuracy is checked to ensure that the water is electrically neutral (hence the term, *charge balance*). For an ideal charge balance, the sum of the anions in milliequivalents per liter (meq/L) should equal the sum of cations in meq/L (Hounslow, 1995).

The charge balance is usually expressed by the equation:

$$\textbf{Balance} = (\sum \text{cations} - \sum \text{anions}) / (\sum \text{cations} + \sum \text{anions}) * 100$$

If the calculated cation-anion balance is less than 10 percent, then the data are assumed to be accurate. If the resulting balance is greater than 10 percent, then one or more of the following conditions may apply:

- the data are inaccurate
- other constituents, such as trace metallic ions or organic ions, may have been present that were not analyzed
- the water was very acidic and hydrogen ions were not present.

Another accuracy check is the ratio of the total cations/total anions, which is also calculated in meq/L. If the ratio equals 1.0, or is at least between 0.90 and 1.10, the data are considered to be accurate. Because a limited number of cations and anions were analyzed, a cation-anion balance of less than 10 percent is assumed to be accurate. Results of the charge balance and cation/anion ratio are provided in Table 13.

**Table 13. Charge and Cation-Anion Balance for Groundwater Data Accuracy**

| Well Designation | Aquifer Screened | Total Cation/Anion Ratio | Target Ratio Accuracy | Charge Balance (%) | Target Balance Accuracy % |
|---|---|---|---|---|---|
| Darwin | Paso Robles | 0.84 | 0.9-1.10 | -8.81 | ≤ 10 |
| Military | Paso Robles | 0.91 | 0.9-1.10 | -4.851 | ≤ 10 |
| Seaside Mid. School | Paso Robles | 0.96 | 0.9-1.10 | -2.13 | ≤ 10 |
| MRWPCA MW-1 | Paso Robles | 1.018 | 0.9-1.10 | 0.87 | ≤ 10 |
| FO-7 Shallow | Paso Robles | 1.32 | 0.9-1.10 | 13.61 | ≤ 10 |
| PRITW Mission | Paso Robles | 0.84 | 0.9-1.10 | -8.70 | ≤ 10 |
| City of Seaside Muni 4 | Paso Robles | 0.97 | 0.9-1.10 | -1.44 | ≤ 10 |
| ASR-2 | Santa Margarita | 1.17 | 0.9-1.10 | 7.93 | ≤ 10 |
| ASR-3 | Santa Margarita | 0.78 | 0.9-1.10 | -12.65 | ≤ 10 |
| Ord Terrace Shallow | Santa Margarita | 0.94 | 0.9-1.10 | -3.15 | ≤ 10 |
| Ord Terrace Deep | Santa Margarita | 1.01 | 0.9-1.10 | 0.61 | ≤ 10 |
| ASR-1 (SMTIW) | Santa Margarita | 1.04 | 0.9-1.10 | 1.82 | ≤ 10 |
| Seaside Middle School | Santa Margarita | 0.84 | 0.9-1.10 | -8.23 | ≤ 10 |
| FO-7 Deep | Santa Margarita | 1.04 | 0.9-1.10 | 1.94 | ≤ 10 |
| ASR MW-1 | Santa Margarita | 1.037 | 0.9-1.10 | 1.82 | ≤ 10 |
| Paralta | Both | 1.016 | 0.9-1.10 | 0.80 | ≤ 10 |
| Ord Grove | Both | 2.00 | 0.9-1.10 | -0.12 | ≤ 10 |
| ASR Injectate | Treated Surface Water | 1.02 | 0.9-1.10 | 0.81 | ≤ 10 |
| GWR Pilot Water | GWR Pilot Plant | 1.05 | 0.9-1.10 | 2.50 | ≤ 10 |

As shown in Table 13, most of the data are within acceptable limits for both the cation/anion ratio and the charge balance. Wells with data slightly outside of the target accuracy limits (shaded values on Table 13 for either cation/anion ratio or charge balance) include Darwin, FO-7 shallow, PRTIW Mission, ASR-2, ASR-3, Seaside Middle School, and Ord Grove. In addition, the groundwater sample from FO-7 Shallow was associated with elevated turbidity that has likely interfered with the metals analytical data and impacted the accuracy check above. Results indicate that the data for wells that do not meet accuracy criteria are most susceptible to inaccurate metals analysis, but are still usable for overall water chemistry. For the purposes of this analysis, all data summarized in Table 13 are presented and reviewed; where water chemistry interpretations are consistent with other data sets in the same aquifer, data are judged reasonable for inclusion. Metals concentrations for the samples that do not meet accuracy criteria are judged less reliable and are not used solely for characterizations of water quality.

#### 7.3.2.3. Water Source Geochemical/Fingerprinting Diagrams

***Stiff Diagrams*** are straight-line plots of cation and anion concentrations in meq/L. Data points are plotted along four parallel horizontal axes on each side of a vertical axis.

Individual points are then connected to produce a polygonal pattern. The patterns or shapes of the polygons can be compared to typical standard patterns for groundwater or seawater or compared to polygons from other wells to identify samples of similar water chemistry. The most recent water quality samples (2009 – 2014) from the combined database were plotted as Stiff diagrams and displayed on a Proposed Project Injection Well Facilities study area map as shown on Figure 16. Diagrams are color-coded to indicate the well construction and the aquifer represented by the polygons. Yellow and green Stiff diagrams indicate a well screened in the Paso Robles Aquifer or the Santa Margarita Aquifer, respectively, while the orange Stiff diagrams indicate screens in both aquifers. Also shown on the map is a Stiff diagram representing the treated Carmel River water injectate for the ASR wellfields (labeled ASR injectate).

The stiff diagrams on Figure 16 show differences in the groundwater signatures between the shallow (Paso Robles) and deep (Santa Margarita) aquifers in the Seaside Basin. In general, wells screened in the Paso Robles Aquifer show lower concentrations of major ions, especially sodium (Na) and potassium (K), calcium (Ca), chloride (Cl), and bicarbonate ($HCO_3$). Concentrations of these ions are consistently higher in the deeper Santa Margarita Aquifer. Wells that are screened in both aquifers show a signature more similar to the deeper Santa Margarita water signature, indicating that the Santa Margarita Aquifer is contributing more water to the well than the Paso Robles Aquifer.

The ASR injectate has a geochemical signature that is different from most of the aquifer signatures in the basin. Because the injectate is sourced from surface water (i.e., the Carmel River system water), the water chemistry is less mineralized than the Seaside Basin ambient groundwater. The ionic concentrations for the ASR injectate are lower than in the Santa Margarita Aquifer and the injectate appears to have slightly higher magnesium and sulfate content than most wells in the Paso Robles Aquifer. Although not clearly demonstrated by the Stiff diagrams on Figure 16, recent TDS concentrations in the ASR-1 and ASR-2 wells indicate mixing with the injectate (HydroMetrics, March 2014).

***Trilinear (Piper) Diagrams*** allow characterization of water chemistry and comparison of water quality analyses. Cation (Ca, magnesium (Mg), and Na+K) concentrations in meq/L are expressed or normalized as a percentage of the total cations, which are plotted on a triangle in the lower left portion of the diagram. Total anions (carbonate ($CO_3$)+$HCO_3$, sulfate (S), and Cl) are plotted on a triangle in the lower right portion of the diagram. The cation-anion plots are then projected onto a central diamond-shaped area, combining both cation and anion distributions. Groundwater with similar geochemistry will generally plot together in similar locations; therefore, groundwater from different sources may be identified by their bulk or intrinsic chemical compositions, which also may be classified as to water type.

The water quality analytical data from the Proposed Project Injection Well Facilities study area wells are plotted on the Trilinear diagram on Figure 17. Data from wells screened in the Paso Robles (yellow) Aquifer, the Santa Margarita Aquifer (green), and both aquifers (orange) are color-coded on the diagram to facilitate aquifer comparisons. Data from an ASR injectate sample (blue) and a sample from the Proposed Project recycled water (GWR) pilot plant (purple) are also included for comparison. Details of the sample from the GWR pilot plant are provided in section 7.3.4.

The Trilinear diagram (Figure 17) shows that groundwater in both aquifers range from neutral-type to sodium-potassium-type (for cations) and bicarbonate-carbonate-type, to neutral-type, to chloride-type (for anions). In the diamond portion of the diagram, the groundwater samples from both shallow and deep aquifers are generally clustered together toward the center, suggesting that shallow aquifer groundwater is mixing with deep aquifer groundwater. There is some slight differentiation among the two aquifers. Most of the groundwater samples from the Paso Robles wells (yellow) group toward a more sodium-chloride (saline) signature (Figure 17).

The ASR injectate appears slightly different from the groundwater signature, especially with respect to bicarbonate (lower) and sulfate (slightly higher). Several samples from ASR wells plot close to the ASR injectate sample, indicating mixing of the two waters.

The GWR pilot plant recycled water plots as sodium-potassium-type and bicarbonate-carbonate-type mostly because of the added calcium carbonate, calcium chloride and carbon dioxide gas used to stabilize the AWTF water. The signature appears more chemically distinct and plots near the edge of other data points.

***Schoeller (Water Source/Fingerprint) Diagrams**.* Although the Trilinear diagram may be used to differentiate between some water chemistry signatures, differences are often indistinguishable except in percentage amounts. Schoeller diagrams plot the actual concentrations in meq/L of specific cations and anions and can offer a more detailed assessment of water chemistry. Schoeller diagrams are therefore used in conjunction with Trilinear diagrams for typing or fingerprinting different water sources. In general, water from similar sources (e.g., sources may include surface water, groundwater influenced by surface recharge, regional older groundwater) will often plot in a similar pattern on a Schoeller diagram. Cations and anions are shown on the diagram's x-axis while actual concentrations are depicted on the diagram's y-axis. Concentration points are then connected providing a "linear" pattern or "fingerprint" for each analysis.

Figure 18 shows the Schoeller diagram analysis for the Proposed Project Injection Well Facilities study area wells. Samples are color-coded similar to the Trilinear diagram to facilitate analysis. ASR injectate and GWR pilot plant recycled water analyses are also shown for comparison purposes.

The Schoeller diagram confirms the interpretation from the Stiff diagrams in that the Paso Robles Aquifer (yellow) contains groundwater at lower ionic concentrations than the Santa Margarita Aquifer (green). For wells screened in both aquifers (i.e., Paralta, Luzern, and Ord Grove – shown in orange), the Schoeller signature is more similar to the Santa Margarita Aquifer, indicating more contribution from that aquifer to the well sample. However, because there is some overlap in the signatures, it also appears that there is infiltration/mixing of groundwater from the upper to lower aquifer.

The ASR injectate (blue) also appears to be influencing the Santa Margarita Aquifer. GWR pilot plant recycled water, shown for future comparison purposes only, has a unique signature with lower concentrations of Mg and $SO_4$. This signature is similar to Schoeller signatures for advanced treated (RO) water samples that Todd Groundwater has observed for other recycled water projects.

***Brine Differentiation (BDP) Plots***. The Brine Differentiation Plot (BDP) was developed by Hounslow (1995) to differentiate brine-contaminated waters from waters of other origins using major constituents commonly available in a water quality analysis. Molar concentrations of calcium divided by calcium plus sulfate on the vertical axis and sodium divided by sodium plus chloride on the horizontal axis are plotted on this type of diagram. The BDP also allows for waters to be plotted in a finite range from 0 to 1.0 on both axes and to determine mixing lines if present. Also, fields for brines, evaporates (i.e., precipitated salts), and seawater can be delineated. One of the advantages of the BDP is that straight- and curved-line mixing ratios can be shown, particularly if end member concentrations (such seawater or brackish water) are known.[9] To determine different water sources, the BDP can be used in conjunction with the Schoeller Diagram.

The BDP on Figure 19 for study area wells shows scattered analytical data without a discernible straight- or curve-line mixing of groundwater. However, the ASR injectate plots close to the ASR wells as expected and plots in a distinct area from other wells. The BDP appears to be a better indicator than the other plots of the mixing of injectate with groundwater in the ASR wells where most of the injection has occurred (ASR-1 and ASR-2). Finally, it is important to note that the GWR pilot plant sample signature is quite distinctive and separate, confirming the Schoeller Diagram signature. These data indicate that Proposed Project product water will be sufficiently distinct from groundwater to allow for use as an intrinsic tracer in tracking the injected recycled water in the subsurface. An *intrinsic tracer* refers to a naturally occurring constituent or compounds already present in water that can distinguish the sample from ambient groundwater. The term is used in opposition to an *extrinsic tracer* – one that is artificially introduced into groundwater (e.g., boron). Per the SWRCB Regulations, the tracer study conducted to validate residence time can use an intrinsic tracer if approved by the Division of Drinking Water and with a safety factor applied (0.67 month credit per month of time estimated using the intrinsic tracer).

#### 7.3.2.4. Concentrations of TDS in Groundwater

As indicated from the geochemical analysis, the ionic concentrations and water chemistry signatures are generally distinct between the Paso Robles and the Santa Margarita aquifers. This interpretation is also mirrored in the concentrations of TDS in groundwater in the Proposed Project Injection Well Facilities study area. Figure 20 shows a map of recent (2012 - 2014) TDS concentration ranges for the samples used in the analysis.

Using the data ranges in the legend, Figure 20 indicates that all of the TDS measurements in the wells were below the California secondary maximum contaminant level (MCL) Upper

[9] End members are waters having two distinct isotopic or chemical compositions with other samples ranging between the two.

Consumer Acceptance Contaminant Level Range of 1,000 mg/L, although some were above the Recommended Consumer Acceptance Contaminant Level Range of 500 mg/L. TDS levels ranged from 190 mg/L in FO-7 Shallow (Paso Robles Aquifer) to 668 mg/L in ASR-2 (Santa Margarita Aquifer). In general, wells screened in the Paso Robles Aquifer have lower TDS concentrations than in the Santa Margarita Aquifer with the 500 mg/L level serving as a reasonable dividing concentration for comparative purposes. For example, all wells screened only in the Paso Robles Aquifer are below 500 mg/L (green on Figure 20). Most of the Santa Margarita wells have recent concentrations above 500 mg/L (yellow on Figure 20), except Paralta (screened in both aquifers), SMS Deep, ASR-3, and FO-7 Deep. The wells did not show a wide variation in TDS concentrations over time.

### 7.3.3. Potential Constituents of Concern and Other Groundwater Analyses

To supplement the characterization of general groundwater chemistry, the water quality database was reviewed for potential constituents of concern defined for this assessment as regulated constituents (those with MCLs) and constituents associated with former military activities at Fort Ord. Some of these constituents had not been analyzed previously in groundwater beneath the Proposed Project Injection Well Facilities area. To address this data gap, groundwater from the six wells sampled in the field program (Table 12 in Section 7.2.1.3) have been analyzed for more than 300 constituents/parameters. In addition to regulated constituents and former Fort Ord constituents, the six groundwater samples were also analyzed for CECs as defined in the SWRCB Recycled Water Policy and other constituents not previously monitored routinely in local groundwater.

#### 7.3.3.1. Constituents Exceeding California Primary MCLs

For the more than 300 constituents and parameters analyzed in each of the six wells for this monitoring event, only two wells, FO-7 Shallow and MRWPCA MW-1, detected any constituents that did not meet the California primary MCLs for drinking water standards. These detections, along with turbidity values, are summarized in Table 14.

## Table 14. Constituents Exceeding California Primary MCLs

| Analyte | Method | Units | MDL | FO-7 Deep | FO-7 Shallow | MRWPCA MW-1 | California Primary MCL |
|---|---|---|---|---|---|---|---|
| **Turbidity** | **SM2130B** | **NTU** | **0.040** | **10** | **550** | **71** | **5*** |
| Aluminum (Al) | EPA 200.8 | µg/L | 8.0 | | 3,700 | 2,700 | 1,000 |
| Arsenic (As) | EPA 200.8 | µg/L | 0.28 | | 210 | | 10 |
| Barium (Ba) | EPA 200.8 | µg/L | 0.12 | | 1,200 | | 1,000 |
| Chromium (Cr) Total | EPA 200.8 | µg/L | 0.32 | | 790 | | 50 |
| Lead (Pb) Total | EPA 200.8 | µg/L | 0.080 | | 42 | | 15 |
| Gross Alpha | 7110B | pCi/L | 3.00 | | 125 ±5 | | 15 |
| Gross Beta | 7110B | pCi/L | 4.0 | | 114 ±2 | | 50 |
| Combined Radium | calculated | pCi/L | 1.00 | | 38.3 ±2.4 | | 5 |

*5 NTU is a secondary MCL; turbidity is included on the table for comparison purposes only.

As shown in Table 14, the only constituents that were analyzed at concentrations above primary MCLs were five metals and several radiogenic parameters. These constituents are the ones most affected by elevated turbidity in groundwater samples; as shown on the table, the well with the most exceedances (FO-7 Shallow) is the well with the highest turbidity value (550 NTU). Further, the only other well with an exceedance (MRWPCA MW-1) also detected elevated turbidity (71 NTU). FO-7 Deep did not detect any constituents above primary MCLs, but the slightly elevated turbidity value of 10 NTU correlated to slightly elevated detections in other metals (see Appendix D, Table D-1B). No exceedances of primary MCLs were recorded in any of the wells with turbidity values of 10 NTU or less.

Due to the relatively slow velocities within groundwater systems and the natural filtering associated with aquifer materials, groundwater does not typically contain solids that would result in the elevated turbidity values shown above. Rather, it is more likely that aquifer particles or other solids are being entrained in the groundwater samples and interfering with the laboratory analysis. Collectively, these data indicate that suspended small particles of aquifer material or pre-development solids are being analyzed by the laboratory methods (i.e., causing analysis interference) rather than dissolved constituents on which water quality standards are based. Therefore, the concentrations of certain metals and radiogenic parameters are not representative of actual concentrations in groundwater.

As previously discussed, the small-diameter casings and deep water table have limited the ability to develop these three monitoring wells in order to produce a turbid-free groundwater sample for analysis. As such, future sampling programs will incorporate techniques such as field filtering to minimize the effects of turbidity.

#### 7.3.3.2. Former Fort Ord Constituents

Given the historical land use of the former Fort Ord lands, the MRWPCA field program included groundwater analyses for chemicals of concern associated with former Fort Ord activities. The six groundwater samples from the MRWPCA field program were analyzed for 17 explosive compounds (nitroaromatics and nitramines) by U.S. EPA Method 8330B. In addition, two metals associated with explosive compounds (beryllium and lead) were also analyzed. These data were compared to available California primary drinking water MCLs and California Notification Levels (NLs)[10] and are summarized in Table 15.

---

[10] NLs are non-regulatory, health-based advisory levels established by the SWRCB Division of Drinking Water (formerly CDPH) for contaminants in drinking water for which MCLs have not been established. A NL represents the concentration of a contaminant in drinking water that the Division of Drinking Water has determined does not pose a significant health risk, but warrants notification to the local governing body.

## Table 15. Groundwater Analyses for Explosives and Associated Metals

| Constituent | Wells with Detections* | Minimum Reporting Limit (RL) | Detected or Reported Concentration | California Primary MCL | California NL | Comments |
|---|---|---|---|---|---|---|
| | | µg/L | | | | |
| **Explosives*** | | | | | | |
| HMX (cyclotetramethylene tetranitramine) | None | 0.099-0.12 | ND | None | 350 | |
| RDX (cyclotrimethylene trinitramine) (cyclonite) | None | 0.099-0.12 | ND | None | 0.3 | |
| 1,3,5- TNB (trinitrobenzene) | None | 0.20-0.22 | ND | None | None | |
| 1,3-dinitobenzene | None | 0.098-0.12 | ND | None | None | |

**Notes:**

* Nitroaromatics and nitramines by U.S. EPA Method 8330B: Samples received and submitted by Alpha Analytical Laboratory, Ukiah, CA to ALS Environmental (ALS), Kelso, WA on February 5, 2014; analyzed by ALS on February 8, 2014.

****** Metals by U.S. EPA Method 200.8 analyzed by Alpha Analytical Laboratory, Ukiah, CA, February 5-11, 2014.

***Constituent also detected in laboratory blank indicating a laboratory contaminant that may not be present in groundwater. All detections were below Reporting Limits (J values) and are not quantifiable.

ug/L = micrograms per liter or parts per billion (ppb)

MCL = Maximum Contaminant Level for drinking water

ND = Not detected above the method detection level for any of the samples from the six wells.

As shown in Table 15, the only explosive constituent detected in groundwater samples was 2,6-DNT (dinitrotoluene). This constituent was also detected in laboratory blank samples, which are samples of laboratory water (not groundwater) analyzed for quality assurance/quality control (QA/QC) purposes. Detections of this constituent at similar levels in the laboratory blank sample indicate that 2,6-DNT is likely a laboratory contaminant and not actually present in groundwater. Although the constituent may be present in several groundwater *samples*, the laboratory blank data suggest that it was introduced into the samples in the laboratory. Further, detections of 2,6-DNT in FO-7 Shallow, FO-7 Deep, and ASR MW-1 were below the laboratory reporting level (RL), meaning that the concentration of 2.6-DNT in samples is too low to be quantified. Given the laboratory QA/QC data for 2,6-DNT, the low levels of the detections, and the absence of additional explosives in groundwater, data indicate that groundwater has not been impacted locally from explosives associated with former Fort Ord activities.

For the metals analysis, both beryllium and lead – as naturally occurring substances – were detected in several groundwater wells above the reporting limits. Beryllium was detected in groundwater collected from ASR-2, FO-7 Shallow, and MRWPCA MW-1, although all of the detections met the California Primary MCL for drinking water. Other wells in the database did not detect beryllium above the laboratory reporting limits.

Lead was also detected in groundwater collected from ASR-1, ASR-2, FO-7 Shallow, FO-7 Deep, Mission Memorial PRTIW, MRWPCA MW-1, and Paralta. The detection in FO-7 Shallow (42 ug/L) was above the MCL (15 ug/L), but appears anomalous with respect to other detections of lead in the database. The concentration of 42 ug/L is the highest concentration in the database by an order of magnitude, which included lead analyses from 13 wells sampled from 2011 through 2014. The second highest concentration was detected in ASR-2 at 3.0 ug/L (also included on Table 15). Except for FO-7 Shallow, all of the detections were below the MCL for lead.

As previously mentioned, the 2014 sampling of FO-7 Shallow was the first time that this small-diameter monitoring well had been sampled for water quality since its original sampling upon well completion. Sampling produced a highly turbid sample (550 NTU), likely relating to the inability to properly develop the well when installed in 1994 as a water level monitoring well. As such, the metals analytical data are likely the result of particle interference and are not likely representative of dissolved lead concentrations in groundwater.

Given the absence of explosives and the relatively low levels of beryllium and lead (with the exception of FO-7 Shallow where data appear to be inaccurate as explained above), the data do not indicate that former Fort Ord activities have impacted groundwater in the existing wells near the Proposed Project Injection Well Facilities site.

#### 7.3.3.3. Constituents of Emerging Concern

As defined in the Recycled Water Policy, constituents of emerging concern (CECs) are chemicals in personal care products (PCPs), pharmaceuticals including antibiotics, antimicrobials, agricultural and household chemicals, hormones, food additives, transformation products and inorganic constituents. These chemicals have been detected in trace amounts in surface water, wastewater, recycled water, and groundwater and have been added to the monitoring requirements for any project involving recharge of recycled water.

The SWRCB Recycled Water Policy CEC monitoring requirements were based on the recommendations of an expert panel. As part of the SWRCB Regulations for injection projects, a project sponsor must recommend CECs for monitoring in recycled water and groundwater in the Engineering Report in addition to the Recycled Water Policy CEC requirements. For injection projects that produce recycled water using RO and AOP, the monitoring requirements in the Recycled Water Policy only apply to recycled water prior to and after treatment (no groundwater sampling). The following CECs are health-based indicators, treatment/performance based indicators, or both as shown below:

- 17-*β*-estradiol - steroid hormone (health-based indicator)
- Caffeine – stimulant (health-based and performance-based indicator)
- N-nitrosodimethylamine (NDMA) – disinfection byproduct (health-based and performance-based indicator)
- Triclosan – antimicrobial (health-based indicator)
- N,N-diethyl-metatoluamide (DEET) – personal care product (performance-based indicator)
- Sucralose – food additive (performance-based indicator)

None of the CECs currently have either primary MCLs for drinking water. For NDMA, the current NL is 0.01 μg/L.

To provide baseline conditions for these CECs in the Seaside Groundwater Basin, the six wells sampled in the recent MRWPCA field program were analyzed for the six CECs and other pharmaceuticals/PCPs included in U.S. EPA Laboratory methods 1625M and 1694 (APCI and ESI+). Groundwater samples were analyzed from ASR MW-1, City of Seaside 4, FO-7 Shallow, FO-7 Deep, PRTIW Mission Memorial, and MRWPCA MW-1. Full results are provided in Appendix D, Table D-1N. Detections of the six CECs are summarized in Table 16.

## Table 16. Groundwater Sample Analyses for CECs

| Constituent* | Wells with Detections** | Minimum Reporting Limit (RL) | Detected or Reported Concentration | Comments |
|---|---|---|---|---|
| | | µg/L*** | | |
| NDMA (nitrosodimethylamine) | PRTIW (Mission Memorial) | 0.002 | 0.0054 | NL =0.01 |
| 17-β-estradiol | None | 0.001 | ND | |
| Triclosan | None | 0.002 | ND | |
| Caffeine | FO-7 Deep | 0.001 | 0.0027 | |
| | MRWPCA MW-1 | | 0.0068 | |
| DEET (n,n-diethyl-m-toluamide) | FO-7 Deep | 0.001 | 0.0023 | |
| | MRWPCA MW-1 | | 0.0060 | |
| Sucralose | None | 0.005 | ND | |

**Notes:**

* NDMA by EPA Method 1625M; 17-β-estradiol and triclosan by EPA Method 1694-APCI; caffeine, DEET, and sucralose by U.S. EPA 1694-ESI+.

** Groundwater analyzed from wells ASR-1, City of Seaside 4, FO-7 Shallow, FO-7 Deep, PRTIW Mission Memorial, and MRWPCA MW-1.

*** Analyses reported on laboratory analytical data sheets in nanograms per liter (ng/L) or parts per trillion. Converted to micrograms per liter (µg/L) or parts per billion (ppb).

Samples received by Alpha Analytical Laboratory, Ukiah, CA; submitted to Weck Laboratories, Inc. (Weck), City of Industry, CA, on February 5, 2014; analyzed by Weck from February 11 to February 19, 2014.

MCL = Maximum Contaminant Level for drinking water.

ND = Not detected.

NL = Notification level.

As indicated in Table 16, NDMA was detected in groundwater collected from the PRTIW well at 0.0054 µg/L (below the NL); caffeine was detected in FO-7 Deep and MRWPCA MW-1 at 0.0027 and 0.0068 µg/L, respectively (below the Drinking Water Equivalent Level [DWEL] of 0.35 µg/L per Anderson et al., 2010).[11] DEET was detected in FO-7 Deep and MRWPCA MW-1 at 0.0023 and 0.0060 µg/L, respectively (below the DWEL of 81 µg/L per Intertox, 2009). Estradiol (17-β), triclosan, and sucralose were not detected above reporting limits in groundwater collected from any of the six wells.

These data represent the first time that CECs have been analyzed in the Seaside Basin and serve as initial background data. The data will be confirmed through future groundwater sampling events that will support the monitoring program proposed in the Proposed Project's Engineering Report. Nonetheless, only a few constituents were detected at very low levels (all less than 0.01 ug/L) and meet advisory or safe health concentrations.

[11] The DWEL is the amount of a substance in drinking water that can be ingested daily over a lifetime without appreciable risk.

#### 7.3.3.4. Local Anthropogenic Impacts or Contaminant Plumes

A search of the study area was conducted on the California Department of Toxic Substances Control (DTSC) *EnviroStor* web site (www.envirostor.dtsc.ca.gov) and the SWRCB *Geotracker* web site (http://geotracker.waterboards.ca.gov). The goal of the search was to identify any potential industrial sites or activities that could contribute to groundwater contamination from previous site uses, spills, and/or chemical releases in the Proposed Project Injection Well Facilities study area.

Both *EnviroStor* and *Geotracker* listed the 28,016-acre Fort Ord Military Reservation as an active Federal Superfund site and listed munitions as the contaminant of primary concern. Additionally, *Geotracker* identified two adjacent sites on the former Fort Ord lands as gasoline contamination sites: (1) the 14th Engineers Motor Pool and (2) Building 511. These are active sites currently undergoing investigations and are located about 1.8 miles to the northeast. However, both sites are outside of the groundwater basin and are not a threat to groundwater in the Proposed Project Injection Well Facilities area.

Other environmental sites have been identified in the basin, including numerous leaking underground storage tank sites, but none were in the Proposed Project Injection Well Facilities area. Specifically, there were no environmental contaminant sites identified in the area between Proposed Project recharge and downgradient extraction wells. Replenishment activities would not be expected to impact any contaminant plumes, if any, located outside of this area.

### 7.3.4. Proposed Project Recycled Water Quality

Trussell Technologies, Inc. (Williams, et al., 2014) provided recycled water samples to Todd Groundwater in support of the MRWPCA field program. The samples were developed to represent the Proposed Project product water quality for the purposes of laboratory tests and geochemical analyses. The samples were RO permeate collected from the MRWPCA GWR pilot advanced water treatment plant. Trussell Technologies stabilized the RO permeate using a bench-scale post-treatment stabilization unit to better approximate the water quality anticipated for the product water from the proposed AWTF.

To develop the bench-scale water samples, Trussell Technologies used several strategies for full-scale RO permeate stabilization to mimic goals established for the OCWD's Groundwater Replenishment System (GWRS), a similar project that used advanced treatment to meet regulatory requirements. (See Section 3.3.6.2, for more information on the OCWD's GWRS) The first chemical stabilization step consisted of the addition of calcium as calcium chloride ($CaCl_2$) and sodium hydroxide (NaOH) to increase alkalinity. Then, $CO_2$ gas was bubbled into the RO water to decrease the pH to a target goal. This process produced approximately 32 L of product water for incorporation into the field program.

These samples - referred to herein as stabilized pilot water samples or pilot water - closely represent the final Proposed Project recycled water quality for the purposes of the field program objectives. The primary objective was to use representative recycled water samples to conduct laboratory leaching tests on vadose zone cores. These data have supported geochemical modeling (summarized in the following sections). Details of the leaching tests and geochemical modeling results are presented in a separate report on the field program (Todd Groundwater, February 2015).

To support the EIR impacts analysis herein, the GWR pilot plant water samples were also analyzed for general minerals, physical characteristics, and metals. The GWR pilot plant water was analyzed by McCampbell Analytical Laboratory. The analytical methods and sample results are presented in Table 17.

### Table 17. Stabilized Pilot Water Analysis

| Analyte | Method | Units | Reporting Limit (RL) | Results | MCL or NL | Basin Plan Objective or Guideline[e] |
|---|---|---|---|---|---|---|

f. Part of SAR determination.

### 7.3.5. Geochemical Compatibility Analysis

When two water types with different water chemistry are mixed (such as the Proposed Project recycled water and groundwater), the compatibility of the waters requires examination. Geochemical reactions in the groundwater system in the vicinity of the well and in the aquifer beyond could potentially result in precipitation or dissolution of constituents (e.g., precipitation of silica or dissolution of metals). These reactions could contribute to clogging in the well and/or pore throats or alter groundwater quality thorough dissolution in the vadose zone or aquifer. In particular, injection in the vadose zone could lead to leaching of natural or anthropogenic constituents that could impact groundwater quality. A geochemical assessment is also helpful in identifying potential adverse reactions that may lead to well scaling or biofouling.

The potential for geochemical incompatibility would be addressed at the proposed AWTF by including a stabilization step in the treatment process to ensure that recycled water is stabilized and non-corrosive. Other injection projects such as the OCWD GWRS provide chemical stabilization for these purposes. Further, no adverse impacts have been observed at the nearby ASR wellfields where ASR injectate has a different water chemistry than native groundwater; this injectate has some similar components of water chemistry to the Proposed Project recycled water that are relevant to compatibility.

To estimate geochemical issues that would need to be addressed through treatment design or operational adjustments at the AWTF, a geochemical assessment was performed using the data from the MRWPCA field program (Todd Groundwater, February 2015). The GWR pilot plant water was provided to McCampbell Laboratories under chain of custody protocol to use in laboratory leaching tests on vadose zone core samples. Stabilized GWR pilot plant water was used for the laboratory extraction process of nine core samples and analyzed for a suite of constituents to provide a preliminary estimate of leaching potential. These tests provide a conservative estimate of the potential for leaching constituents from the vadose zone during injection associated with the Proposed Project. The analysis is considered conservative because the GWR pilot plant water is slightly more aggressive (as indicated by the negative value of the Langelier Saturation Index on Table 17) than the anticipated final AWTF water.

Due to the unconsolidated nature of the core samples and limitations with extraction methods, the laboratory results were compromised by elevated turbidity in some of the leachate samples (Todd Groundwater, February 2015). Notwithstanding the limitations of the results, the leaching tests provided valuable information on which constituents represented the highest potential for leaching and identified potential geochemical reactions that warranted further investigation through geochemical modeling.

Geochemical modeling was conducted with a series of PHREEQC and PHAST geochemical model codes by Mahoney Geochemical Consulting LLC, Lakewood, CO (See Appendix G in Todd Groundwater, February 2015). The modeling was used to analyze the potential for dissolution (leaching) of chromium, arsenic, and lead from the vadose zone sediments (including samples from the Aromas Sand and Paso Robles Aquifer).

The modeling indicated that trace amounts of chromium adsorbed onto the hydrous ferric oxide coatings of the sand grains represented the highest potential for leaching. However, this leaching does not represent a long-term effect due to the limited total amount of chromium available in the sediments. The maximum concentration in the zone of saturation was estimated to be about 4.0 ug/L after one year of injection – a concentration substantially below the total chromium MCL of 50 ug/L.

Although arsenic and lead were also determined to be present in vadose zone sediments, those constituents were more strongly adsorbed to the oxides than chromium. Consequently, only small amounts are predicted to be released into solution as the injected water flows through the Aromas Sand, resulting in sustained but low concentrations of about 4 µg/L for arsenic and approximately 0.7 µg/L for lead. Concentrations in the zone of saturation meet water quality standards. None of the analyses indicated that groundwater concentrations would exceed regulatory standards for any of the leached constituents.

Additional geochemical analyses indicated that aquifer clogging from calcite precipitation would be unlikely due to the low concentrations of calcium and bicarbonate. Extensive biofouling of injection wells was also evaluated and determined to be unlikely given that the low concentrations of nitrogen and phosphorus in the AWTF product water would not tend to stimulate microbial growth.

In addition to impacts from the vadose zone wells, the analysis examined the potential for impacts to the Santa Margarita Aquifer from recharge into deep injection wells. Results indicated that the potential for such impacts were unlikely. Risk of trace metal desorption during injection of recycled water into the Santa Margarita Formation was inferred from previous studies of injected Carmel River water. The two injected water types have similar pH and oxidation-reduction potential, and are therefore expected to have similar effects with respect to adsorption/desorption processes. Previous studies found no indications that significant metal concentrations would be released into solution, and those results can reasonably be extended to injection of recycled water.

None of the modeling results indicated that groundwater would be geochemically incompatible with AWTF product water or that the project would have a significant impact on groundwater quality. Complete results of the geochemical analyses and modeling are presented in the draft report on the MRWPCA field program (Todd Groundwater, February 2015).

In addition to this work, to support the assessment of compliance with the SWRCB Regulations and the CRWQCB and the pilot testing, a one-year monitoring program was conducted from July 2013 to June 2014 for five of the potential source waters. Regular monthly and quarterly sampling was carried out for the RTP secondary effluent, agricultural wash water, and Blanco Drain drainage water. Limited sampling of stormwater from Lake El Estero was performed due to seasonal availability, and there was one sampling event for the Tembladero Slough drainage water.

An assessment conducted by Nellor (2015) reviewed the analytical results of source water monitoring, the water quality results of the GWR pilot plant testing (using ozone, MF, and RO), the stabilized RO sample (see Table 17 in this report), information on the predicted performance and water quality of the proposed full-scale AWT Facility based on other existing groundwater replenishment projects, and related research/studies. Based on the results of that assessment, the Proposed Project will comply with the:

- SWRCB Regulations (for groundwater replenishment), including MCLs, NLs, total organic carbon, and other numeric water quality-based requirements; and
- Central Coast Water Quality Control Plan objectives and guidelines for protection of groundwater uses (municipal and domestic water supply, agricultural water supply, and industrial use).

### 7.3.6. Salt and Nutrient Management Plan

A Salt and Nutrient Management Plan (SNMP) has been prepared for the Seaside Basin to comply with requirements in the SWRCB's Recycled Water Policy (HydroMetrics, March 2014). The SNMP was developed with basin stakeholder input through the Seaside Basin Watermaster and has been adopted by the MPWMD Board. The final SNMP has been submitted to the CRWQCB.

As documented in the SNMP and confirmed herein, ambient groundwater generally exceeds Basin Plan objectives for TDS in many areas of the basin, while nitrate and chloride concentrations generally meet Basin Plan objectives. As indicated by the water quality analyses of the stabilized GWR pilot plant water (discussed above), TDS, nitrate, and chloride all meet Basin Plan objectives. Further, these concentrations are generally lower than average concentrations in groundwater. As such, recharge of the Seaside Basin using the Proposed Project recycled water would not adversely impact salt and nutrient loading in the basin and would provide benefits to local groundwater quality.

## 7.4. POTENTIAL GROUNDWATER QUALITY IMPACTS

The assessment of potential impacts from the Proposed Project on local groundwater resources is based on the preceding characterization of groundwater and recycled water.

### 7.4.1. Thresholds of Significance

Appendix G of the 2013 CEQA Guidelines provides the primary question relating to potential GWR impacts on groundwater quality is as follows:

> *Would the project violate any water quality standards or otherwise degrade water quality?*

The following factors were developed for the Proposed Project to clarify how this question would be applied in the impact analyses. Implementation of the Proposed Project would be considered to have a significant impact on groundwater quality if:

- The Proposed Project, taking into consideration the proposed treatment processes and groundwater attenuation and dilution, were to:
    - Impact groundwater so that it would not meet a water quality standard (e.g., Basin Plan beneficial uses and water quality objectives, including drinking water MCLs established to protect public health).
    - Degrade groundwater quality subject to California Water Code statutory requirements for the Division of Drinking Water, and to the SWRCB Anti-degradation Policy and Recycled Water Policy.
- The Proposed Project were to result in changes to basin recharge such that it would adversely affect groundwater quality by exacerbating seawater intrusion.

### 7.4.2. Potential Degradation of Groundwater Quality

As described in the previous sections, the Proposed Project recycled water would be treated and stabilized to meet all drinking water quality objectives. As shown on Table 17 and discussed above, TDS (74 mg/L) and nitrogen (1.3 mg/L as total N) would also meet Basin Plan objectives. Further, the Proposed Project recycled water is expected to be higher quality water than ambient groundwater with respect to TDS, chloride, and nitrate. As such, the Proposed Project would not result in the groundwater failing to meet groundwater objectives or beneficial uses. Rather, the Proposed Project recycled water would have a beneficial effect on local groundwater quality from the injection of high quality water that meets objectives and has low TDS and chloride concentrations.

### 7.4.3. Impacts on Seawater Intrusion

As demonstrated by the modeling by HydroMetrics (Appendix C) and discussed above (Section 7.1.2.2.2), the Proposed Project is not expected to cause water levels to fall below elevations that are protective against seawater intrusion.

The Proposed Project would incorporate operational monitoring to track impacts on water levels from recharge and pumping. Real-time modifications can be incorporated into the operation of the Proposed Project to address any short-term water level declines, if needed. For example, during the primary pumping period, more water can be directed to the deeper aquifer where existing water level declines are more widespread.

The Proposed Project would provide basin replenishment to meet the primary objective of increasing basin production to replace a portion of the CalAm water supply as required by state orders. The impact analysis indicates that the Proposed Project would not exacerbate seawater intrusion. However, it is noted that seawater intrusion cannot be prevented by this project alone. Water levels are below sea level at the coast in the Santa Margarita Aquifer and the Proposed Project would not raise levels over the long term. However, the short term rise in water levels associated with the Proposed Project during the winter when pumping is less will prevent significant water level declines during the summer when pumping increases. A more complete analysis of water level impacts associated with the Proposed Project is provided in the TM in Appendix C.

### 7.4.4. Geochemical Compatibility of GWR Product Water and Groundwater

As discussed in Section 7.3.5 above, the results of the MRWPCA field program and geochemical modeling indicate that injection of project recycled water through both vadose zone wells and deep injection wells will not have a significant adverse impact on groundwater quality (Todd Groundwater, February 2015). A brief summary of key conclusions from the analysis are provided below:

- Chemicals associated with the former Fort Ord activities, including soluble nitroaromatic compounds (explosives), perchlorate, or certain organic constituents, were not detected in core samples or groundwater samples and are not expected to impact groundwater quality.
- Potential changes in injected recycled water quality beneath vadose zone wells from geochemical reactions between recycled water and formation materials along vertical flow paths are small. The analysis of leaching of chromium, arsenic, and lead indicated that concentrations in the zone of saturation are expected to be very low and would meet water quality standards.
- Aquifer clogging by calcite precipitation is unlikely to be a problem for the Proposed Project. In the Aromas Sand, calcium and bicarbonate concentrations are below saturation levels. Ambient groundwater in the Paso Robles Formation is at saturation with respect to calcite, but given the pH of the injected water, calcite would not be expected to precipitate.
- Biofouling would not likely pose a problem for the injection wells because the injected water is very low in nitrogen and phosphorus and would not tend to stimulate microbial growth.
- Based on the water chemistry of the GWR pilot plant water and observations from the ASR wellfield, adverse impacts from geochemical incompatibility are unlikely in the Santa Margarita Aquifer in the vicinity of the deep injection wells.

### 7.4.5. Conclusions of the Impacts Assessment for Groundwater Quality

Based on the groundwater characterization, recent groundwater sampling results, stabilized pilot water quality/chemistry and projected AWTF water quality (i.e., highly treated recycled water), and results from the MRWPCA field program, the following conclusions are offered:

- Stabilized GWR pilot plant water samples and projected AWTF product water meet SWRCB Regulations for groundwater replenishment projects and Basin Plan groundwater quality standards, including drinking water MCLs. Further, the treatment processes that would be incorporated into the AWTF would be selected and operated to ensure that all water quality standards would be met in both the recycled water and groundwater. A monitoring program would document project performance.
- Stabilized GWR pilot plant water samples and projected AWTF product water exhibit much lower concentrations of TDS and chloride than in ambient groundwater and would be expected to provide a localized benefit to groundwater quality. Such a benefit would expand over time with continuous injection from the Proposed Project wells.
- No documented groundwater contamination or contaminant plumes have been identified in the Proposed Project area. Therefore, injection associated with the Proposed Project would not exacerbate existing groundwater contamination or cause plumes of contaminants to migrate.
- Injection of AWTF recycled water would not degrade groundwater quality. A monitoring plan would be implemented to meet CRWQCB and SWRCB Division of Drinking Water requirements.
- The Proposed Project recycled water would be stabilized as part of the AWTF to ensure no adverse geochemical impacts. Geochemical modeling associated with the MRWPCA field program indicated that no adverse groundwater quality impacts are expected from leaching or other geochemical reactions.
- The Proposed Project would result in both higher and lower water levels in wells throughout the basin at various times. Although water levels would be slightly lower during some time periods, the difference is generally small and judged insignificant.
- Modeling indicates that the Proposed Project would not lower water levels below protective levels in coastal wells and would not exacerbate seawater intrusion.

# APPENDIX A

## Todd Groundwater Technical Memorandum Selection of Recharge Location for GWR Project, Seaside Groundwater Basin, May 29, 2014

TODD GROUNDWATER

May 29, 2014

# TECHNICAL MEMORANDUM

**To:** Bob Holden, PE
Monterey Regional Water Pollution Control Agency (MRWPCA)

**From:** Phyllis Stanin, Vice President/Principal Geologist

**Re:** Selection of Recharge Location for GWR Project
Seaside Groundwater Basin

Monterey Regional Water Pollution Control Agency (MRWPCA) has been developing the Groundwater Replenishment (GWR) Project (also, Proposed Project), which involves advanced treatment of various water sources for conveyance and recharge into the Seaside Groundwater Basin (Seaside Basin). In that basin, declining water levels and overdraft conditions have placed drinking water aquifers at risk of seawater intrusion. These conditions have resulted in court-imposed limits on groundwater extraction for drinking water. The Proposed Project offers a reliable source of recharge to increase basin yield without exacerbating the risk of seawater intrusion.

Over the last several years, MRWPCA has considered various locations for recharge in the Seaside Basin. Two preliminary recharge locations were identified and evaluated in 2009 during early project development. The western-most location consists of two parcels along Highway 1 and is referred to as the former Coastal Location (Figure A-1). An eastern location, referred to as the former Inland Location, was delineated as a strip of land along Eucalyptus Road, which crossed the northern boundary of the Seaside Groundwater Basin (Figure A-1). As shown on Figure A-1, the current proposed location is a curved strip of land about 2,000 feet southwest of the former Inland Location. The purpose of this memorandum is to document the selection of the proposed location for implementation of the GWR project.

## BACKGROUND

In 2013, the former Inland Location was re-located to an adjacent parcel approximately 2,000 feet southwest based on hydrogeologic and engineering criteria including:

- ensure that recharged water remains within the Seaside Basin
- locate recharge immediately upgradient of pumping depressions to mitigate declining water levels
- decrease conveyance and pumping costs by re-locating to areas of lower ground surface elevations.

The proposed recharge location (or *proposed location*) consists of a relatively narrow strip of land approximately 3,000 feet in length (Figure A-1). The strip is located along a parcel boundary between proposed development by the City of Seaside and open space associated with former Fort Ord lands. The parcel, currently owned by the Fort Ord Reuse Authority (FORA), will be conveyed to the City of Seaside when remediation activities on certain other former Fort Ord lands have been completed.

Although both the proposed location and former Coastal Location have benefits for the development of the Proposed Project, the proposed location on Figure A-1 has been selected for implementation. That location is currently under evaluation in an Environmental Impact Report (EIR) being prepared by MRWPCA. The selection of the proposed location instead of the former Coastal Location also involved hydrogeologic, engineering, and cost considerations.

In July 2013, the Seaside Basin Watermaster (Watermaster) conducted an evaluation of recharge at various inland and coastal locations, including the southern parcel of the former Coastal Location (Figure A-2). For that evaluation, HydroMetrics WRI (HydroMetrics), applied a basin-wide groundwater flow model to simulate changes in water levels resulting from recharge of various amounts and at various locations within the basin (HydroMetrics, July 19, 2013). That analysis provided technical information relevant to the selection of the proposed location. The results of the Watermaster modeling and the selection of the proposed location are described in this memorandum.

## PROJECT OBJECTIVES

In order to meet the Proposed Project's primary objective of providing recharge to the Seaside Groundwater Basin to replace a portion of Cal-Am's water supply, the Proposed Project must:

- be cost effective
- comply with water quality regulations
- meet Cal-Am's scheduling needs.

Secondary project objectives include:

- assist in preventing seawater intrusion in the Seaside Basin
- assist in diversifying Monterey County's water supply portfolio
- provide additional water that could be used for crop irrigation through the Salinas Valley Reclamation Project and Castroville Seawater Intrusion Project system.

## HYDROGEOLOGIC CONSIDERATIONS

Hydrogeologic conditions at the former Coastal Location were compared to the proposed location in order to select the optimal site for GWR project development as summarized in the following sections.

**Injection Capacity is less certain at the former Coastal Location.**

Different characteristics in hydrostratigraphy of the Santa Margarita Aquifer have been documented at the former Coastal Location that could impact implementation of the Proposed Project. A 2007 field investigation conducted by the Watermaster resulted in an improved understanding of the coastal hydrostratigraphy near the former Coastal Location (Feeney, 2007). During that investigation, four deep monitoring wells were installed along the coast as part of a sentinel monitoring program to protect against seawater intrusion. Two of these wells, SBWM-3 and SBWM-4, are within 2,000 feet and 1,350 feet from the former Coastal Location, respectively. Figure A-2 shows these two wells and the outline of the southern parcel of the former Coastal Location (labeled *MRWPCA South Location*) (HydroMetrics, July 19, 2013).

Data from these two wells indicate significant differences in the Santa Margarita Aquifer compared to inland areas. In brief, the Santa Margarita Aquifer – the primary target for the Proposed Project – may be thin or absent at the former Coastal Location. This interpretation is illustrated on a cross section developed by Feeney (2007). A portion of that cross section including the two monitoring wells close to the former Coastal Location is shown on Figure A-3. The approximate location of the former Coastal Location is projected onto the section. As shown on the figure, the Santa Margarita Aquifer is interpreted to be very thin (less than 100 feet thick) in SBWM-4 and absent in SBWM-3. The section is replaced with a relatively thick sequence of the Purisima Formation. Although the Purisima Formation appears to be hydraulically connected to the Santa Margarita Aquifer and may also function as an aquifer, the formation appears to be less permeable based on geologic and geophysical logs (Feeney, 2007). In addition, the permeability of this unit was assigned a lower hydraulic conductivity value in the basin-wide groundwater flow model (HydroMetrics, 2009).

Decreased permeability would likely result in a lower injection rate, which would require more wells than are currently planned at the proposed location for the same amount of recharge. In addition, injection wells in a low permeability formation may be more susceptible to clogging. Deep aquifers may have limited storage if porosity is also lower. At a minimum, the former Coastal Location would require an additional deep aquifer testing program to determine the feasibility of deep injection wells prior to project implementation. Such a program would negatively impact project objectives by affecting both the cost and schedule of the Proposed Project.

In contrast, the Santa Margarita Aquifer near the proposed location is approximately 300 feet thick, with relatively high permeability. Within about 1,000 feet to 1,300 feet of the proposed location, four successful ASR wells are screened in the Santa Margarita Aquifer and operated for both injection and recovery. These wells have relatively high transmissivity values of about 100,000 gallons per day per foot (gpd/ft) and relatively high specific capacities that range from about 27 gallons per minute per foot of drawdown (gpm/ft dd) to more than 60 gpm/ft dd (Padre, 2002; Pueblo, 2012). These observations suggest that fewer wells would be needed at the proposed location, reducing project costs.

**The Proposed Location is upgradient of existing production wells.**
The water level contour map on Figure A-2 shows contours of the potentiometric surface of the Santa Margarita Aquifer (equivalent to the *Deep Zone* as labeled on the map). Contours indicate that water levels are below sea level throughout the Northern Coastal Subarea and are deeper than -60 feet below mean sea level (msl) in the area of numerous production wells (black circles), forming a pumping depression (Figure A-2). The proposed location is located upgradient of numerous production wells and closer to the pumping depression than the former Coastal Location. Most of the production wells shown in this area are owned and operated by Cal-Am and will be pumped to recover recycled water being recharged by the Proposed Project. Essentially all of the recharged water will flow toward these wells under existing groundwater flow conditions.

**Deeper water table at the proposed location allows more storage in the vadose zone.**
The water table beneath the proposed location occurs at an average depth of about 400 feet below ground surface (bgs). Further, data from a recent MRWPCA field program indicate very high porosity and permeability values in the vadose zone, providing a large storage volume for recharge of recycled water.

In contrast, the water table beneath the former Coastal Location is only about 115 feet bgs. The relatively shallow water table limits vadose zone storage. Under these conditions, mounding of the recharge water could reduce injection rates over time.

**Recharge at the Former Coastal Location would result in project water being lost to ocean outflow.**
Injection in both deep and shallow wells will result in groundwater mounding and radial groundwater flow away from the injection wells. Depending on the then-current water levels, recharged water would flow both inland toward the pumping depression and coastal toward the ocean. This groundwater flow pattern would result in some amount of recharge being lost to ocean outflow that could not be recovered through existing wells. The mound would provide some protection against seawater intrusion that would allow water levels to be lowered inland through increased pumping. However, there is uncertainty associated with the lateral and vertical extent of mounding at the former Coastal Location; it is unclear what adverse impacts would result from allowing water levels to decline inland. In summary, a portion of the recharged water may not be recoverable.

## ENGINEERING AND COST CONSIDERATIONS

In addition to the hydrogeologic considerations, several components of the preliminary GWR project design were factors in the location selection process. For example, a conceptual project design developed in 2009 indicated higher project costs with the former Coastal Location. At that time, both the former Inland and Coastal locations were assumed to connect to the proposed Regional Urban Water Augmentation Pipeline (RUWAP), which enters the basin along General Jim Moore Boulevard as shown on Figure A-1 (see the purple line labeled proposed pipeline). For the former Coastal Location, a connecting pipeline would have to be routed through residential and urban development and then across both parcels of the former Coastal Location. For the former Inland Location (and the proposed location), a connecting pipeline could be routed to Eucalyptus Road. Preliminary costs developed for the water supply lines indicated higher costs for the routing to the former Coastal Location. Given the hydrogeologic uncertainty at the former Coastal Location, more project wells would have to be connected and maintained, also resulting in increased costs.

## GROUNDWATER MODELING

The groundwater modeling conducted by the Watermaster allowed comparison of the effectiveness of various recharge locations for protection against seawater intrusion. Although these simulations were not conducted specifically to evaluate the Proposed Project, the modeling simulates the aquifer response to injection at both inland and coastal locations similar to those evaluated for the Proposed Project. Model results were summarized in a Technical Memorandum titled *Groundwater Modeling Results of Coastal Injection in the Seaside Basin* (HydroMetrics, July 2013). Relevant sections of that memorandum are summarized below.

Two modeling scenarios, referred to as Scenario 0 and Scenario 1, simulated 1,000 AFY of injection at each of two locations including an inland and coastal location. Figure A-2 shows a map from the HydroMetrics memorandum that identifies the modeled injection locations. The simulated coastal locations are shown by red parcels labeled “Modeled Coastal Injection Locations[1]” in the map legend of Figure A-2. The simulated inland location is shown by an arrow (labeled *Inland Injection Location* on Figure A-2) and coincides with the ASR wellfield located near the proposed GWR project location (also labeled on Figure A-2).

The effectiveness of each injection location was judged by the ability to raise water levels in coastal wells to levels protective of seawater intrusion. These protective levels had been established by the Watermaster in previous evaluations (HydroMetrics, December 2013). To illustrate the model results, simulated water levels in a nearby coastal monitoring well cluster, MSC Shallow and MSC Deep, are shown on Figure A-4. Results for other coastal wells vary, but Scenarios 0 and 1 track similarly (with a difference of only a few feet or less) for the four wells presented in the memorandum (HydroMetrics, July 2013). Although the figure contains results from numerous model scenarios (Scenarios 0 through 7 as shown on the legend), Scenario 0 and Scenario 1 are the comparable results from the coastal and inland injection locations. Except for Baseline and Scenario 0, all scenarios involve injection at the coastal location and vary amounts and timing of recharge. Although the curves are difficult to differentiate on Figure A-4, the curves from Scenarios 0 and 1 are labeled and track very closely for both of the well clusters.

Results of the simulations indicate that injection at the former Coastal Location raises coastal water levels higher and faster than inland injection, but only by a small amount (less

[1] The HydroMetrics northernmost coastal location is the same as the southern parcel of the former GWR Coastal Location – compare Figures A-1 and A-2. HydroMetrics reports that modeling results were very similar between the two coastal locations shown on Figure A-2.

than two feet). The memorandum concludes that coastal injection achieves protective water levels one to ten years faster than inland injection, depending on the well. This means that the coastal injection curves labeled on Figure A-4 for both MSC Shallow and Deep reach the line labeled Protective Water Level before the inland injection curves (also labeled on Figure A-4). While this conclusion is correct, the inland injection curves are very close to the line and demonstrate that injection inland is also effective at raising water levels near the coast.

Further, Scenario 5 shows that coastal injection of 1,900 AFY raises water levels very high in both clusters, and within about 35 feet of the ground surface. With the GWR project injection of approximately 3,500 AFY, water levels would rise even higher, suggesting that the former Coastal Location has limited storage. Scenario 4 indicated that protective water levels at the coast could be maintained at about 850 AFY, significantly below the water available for injection for the Proposed Project. In addition, a significant portion of the injected water leaves the basin as coastal outflow, potentially limiting the amount of water that could be recovered.

While the modeling suggests that the former Coastal Location may be slightly more effective at achieving protective water levels in a shorter amount of time, the inland location also raises water levels along the coast and has more storage.

## SUMMARY

Based on the hydrogeologic analysis, preliminary project design including costs, and recent groundwater modeling by the Watermaster, the following conclusions can be made.

- The proposed location provides more hydrogeologic certainty than the former Coastal Location for project development. The Santa Margarita Aquifer may be thin or absent at the former Coastal Location.
- A deep aquifer testing program to reduce this uncertainty would adversely impact the project's schedule and cost.
- More injection wells may be required at the former Coastal Location for the same amount of recharge at an inland location, reducing the cost effectiveness of the project.
- The proposed location is close to proven ASR wells in the Santa Margarita Aquifer with favorable injection rates.
- The proposed location is adjacent to and upgradient of most of the water supply wells that will recover the Proposed Project's recharged water.
- The proposed location provides sufficient storage to accommodate all of the GWR project water. Both locations are not needed. Storage at the former Coastal Location is less certain.
- Injection at the former Coastal Location would increase loss of GWR water to ocean outflow, potentially reducing the amount of GWR water that could be recovered.
- Water supply lines and conveyance costs may be more expensive for the former Coastal Location.

- The proposed location is more supportive of the primary project objectives than the former Coastal Location.
- Although the former Coastal Location may be more effective at meeting the secondary project objective of assistance in preventing seawater intrusion, the proposed location also meets that objective. Specifically, the proposed location supports an increase in basin production without exacerbating the risk for seawater intrusion.

Oakland, CA 94612

Mr. Bob Holden
Monterey Regional Water Pollution Control District
5 Harris Court, Bldg. D
Monterey, CA 93940

October 2, 2013

Subject: Groundwater Replenishment Project Development Modeling

Dear Mr. Holden:

The letter below discusses the results of modeling completed in support of the Groundwater Replenishment Project (GWR) project development efforts.

The GWR is a central component of the Monterey Regional Water Pollution Control Agency's (MRWPCA's) plans to maintain a sustainable supply of fresh water to its customers. The GWR will recharge an average of 3,500 acre-feet (AF) of water into the Seaside groundwater basin throughout the year. This recharge will be matched by an increase of 3,500 AF per year of additional extraction from the basin. While this strategy produces no net change to the average water balance of the basin, the location and the timing of recharge and extraction may alter the flow dynamics of the basin. The impact that the recharged water has, whether it will produce additional storage that can be extracted or whether it force extra water to flow offshore or into the Salinas basin, depends upon the details of the project.

## Background and Approach

Our simulations incorporated certain assumptions about the recharge and pumping. These assumptions were detailed discussed in a letter from HydroMetrics WRI dated August 29, 2013. We assumed the recharge will be distributed evenly throughout the year. The increased pumping will follow a seasonal cycle based upon the observed current seasonal water demand of Cal-

Am customers. The additional extraction of GWR water is projected to occur entirely through six existing wells:

- ASR 1- 4
- Ord Grove #2
- Paralta
- Luzern
- Playa #3
- Plumas #4

Tentative sites have been selected for the placement of GWR vadose zone wells and deep injection wells. Up to four vadose zone wells have been proposed for delivering water into the shallow Paso Robles formation, and up to three deep injection wells have been proposed for injecting water into the deep Santa Margarita formation.

Four model simulations were conducted to investigate the impact of different strategies for recharging the GWR water. These simulations consisted of one baseline scenario in which no GWR water is recharged or extracted, and three scenarios in which the GWR water is recharged to the Paso Robles and Santa Margarita formation in varying proportions. The proportion of water recharged into each formation is shown in Table 1.

**Table 1: Recharge Distribution in Model Scenarios**

| | Percent Recharged into Paso Robles | Percent Recharged into Santa Margarita |
|---|---|---|
| **Scenario 1** | 100% | 0% |
| **Scenario 2** | 0% | 100% |
| **Scenario 3** | 20% | 80% |

The first and second scenario are included as end-member cases to predict the most extreme impacts expected from the project, and to compare the behavior of shallow versus deep injection. The third scenario recharges water in accordance with the historical pumping distribution in the Seaside basin: historically, Cal-Am extracts approximately 80% of its water from the deeper Santa Margarita Formation and 20% from the shallow Paso Robles Formation.

## Model Setup

To model the scenarios, HydroMetrics WRI extended the 2012 TAC baseline model. The baseline model originally simulated the Seaside Basin through 2030. The model was extended from 2030 through 2041 for these simulations. The year 2041 was chosen using the assumption that Cal-Am's repayment would begin in 2017, and the repayment would take 25 years.

All boundary conditions for the added simulation period are held constant at their 2030 levels. These include the general head boundaries along the coast, constant head boundaries adjacent to the Salinas Basin, and all no flow boundaries.

The same hydrology (rainfall and recharge) used in previous model runs was applied to the baseline scenario and all pumping scenarios. To extend the hydrology through the predictive period, the 1987 through 2008 hydrology data were repeated for model years 2009 through 2030, and 2031 through 2041 (Figure 1). Because there are only 22 years of hydrology data between 1987 and 2008, these 22 years have been repeated in succession through 2041. By using this hydrology, even during the period January 2009 to present when actual hydrology is known, the model runs can be used to compare relative groundwater levels but not to assess absolute Basin conditions.

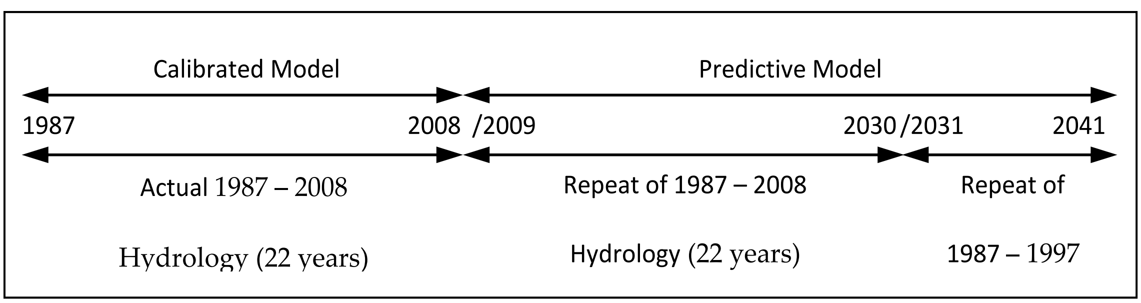

**Figure 1: Repetition of Hydrology for Predictive Model**

Deep injection is simulated in the model as wells that are located in the fifth, and lowest, model layer using MODFLOW's well package. The vadose zone wells are simulated in the model by applying water to the surface of the appropriate model cells using MODFLOW's recharge package. While conceptually the water is applied near the surface, the recharge package will deliver this water to the shallowest layer that remains saturated during any stress period. As a result, the water recharged through the vadose zone wells is not always applied to the top model layer, and the application layer varies throughout the simulation.

## Performance Measures

The GWR's purpose is to provide potable water to Cal-Am. Water recharged by GWR must be available for extraction by Cal am wells. Performance measures must therefore show that the recharged water is not lost to the ocean or nearby basins. Two criteria were used to assess each scenario's performance: whether the project increased outflow to the ocean, and whether the project increased or decreased overall storage in the basin. Because the recharge of GWR water is intended solely for storage and reuse in the short term, we believe that the ideal scenario would result in no long-term changes in the amount of water stored in the basin and would not alter the flow that occurs through any of the basin boundaries. Therefore, the best scenario is the one that is most similar to the baseline.

### Coastal Outflow Criterion

Outflow from the Seaside Basin to the ocean was the primary criterion used to assess project performance. A project that increases the amount of outflow to the ocean is theoretically recharging water that cannot be captured by Cal-Am. The best scenarios are those that do not increase outflow to the ocean.

The amount of water flowing to the ocean was estimated by analyzing the flow at every cell along the model's general head boundary (GHB) that simulates the ocean boundary. These flows were summarized for all cells within boundaries of the adjudicated basin. Only flows directed from the basin to the ocean were summarized: inflow from the ocean was not part of the performance criterion.

Figure 1 through Figure 4 show the results for model layers 1, 3, 4, and all for all layers combined. Layer 2 is not shown because it only experienced inflow and layer 5 is not shown because we have assumed that the Santa Margarita aquifer is not directly connected to the ocean. Each figure comprises two graphs. The top graph shows the overall outflow rates in acre-feet per day for each scenario and for the entire model period. The bottom graph shows the difference in the outflow rate between the recharge scenarios and the baseline scenario. On this figure positive values indicate that a scenario has more outflow than the baseline, and negative values indicate that a scenario has less outflow than the baseline.

Scenario 1, with 100% of recharge occurring through the vadose wells, has the greatest outflow for each of the model layers. Scenarios 2 and 3 have outflows that are much more similar to the baseline, with scenario 2 tending to have less outward flow than baseline and scenario 3 switching between less and more outward flow than baseline over time.

A comparison of the outflow from layer 1 (Figure 1) and the outflow from all layers (Figure 4) reveals that most of the increased total outflow are accounted for by layer 1. This is the layer in which recharge usually occurs, and which is most removed from the deep Santa Margarita formation from which the majority of Cal-Am's water is pumped. This demonstrates that concentrating recharge in the shallow Paso Robles Formation will results in water flowing tot the coast without percolating into the deeper formations.

These results suggest that scenario 2 with 100% of water injected through the deep injection wells will lose the least amount of water to the coast, while scenario 3, with 80% injected through the deep injection wells, and 20% through the vadose wells will have the least overall impact on the flow along the coast.

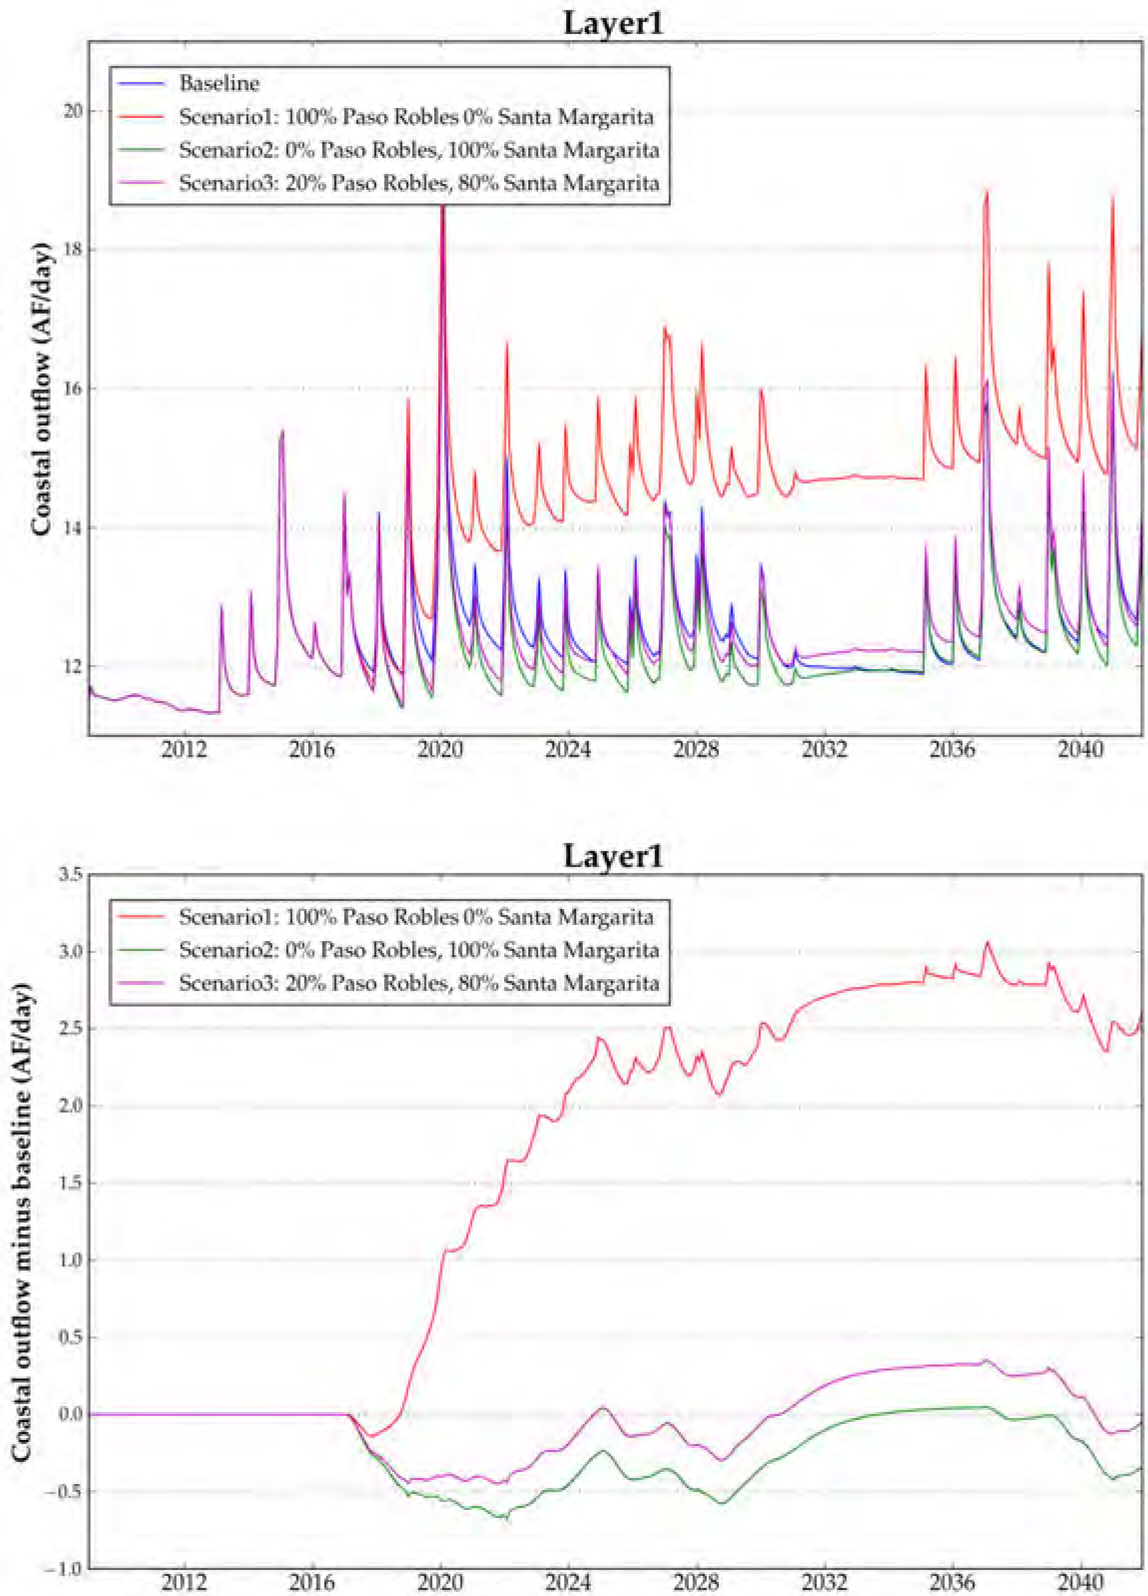

**Figure 1: Coastal Outflow along Layer 1 General Head Boundary**

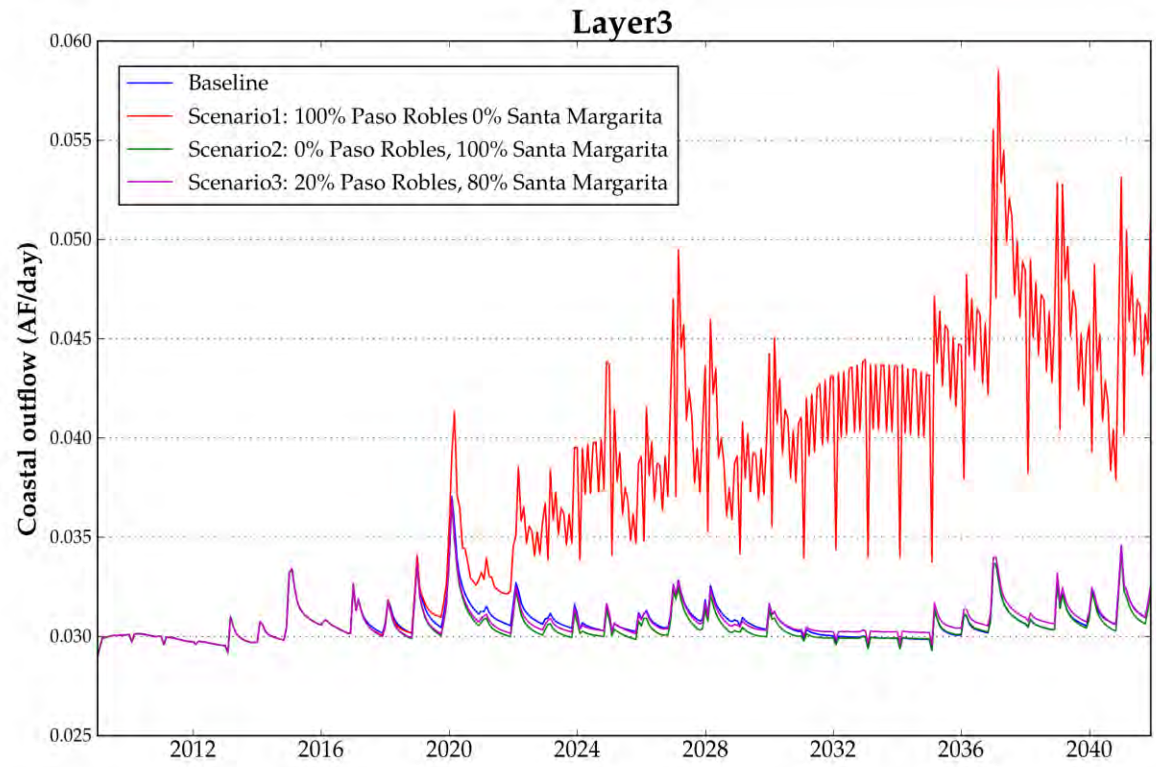

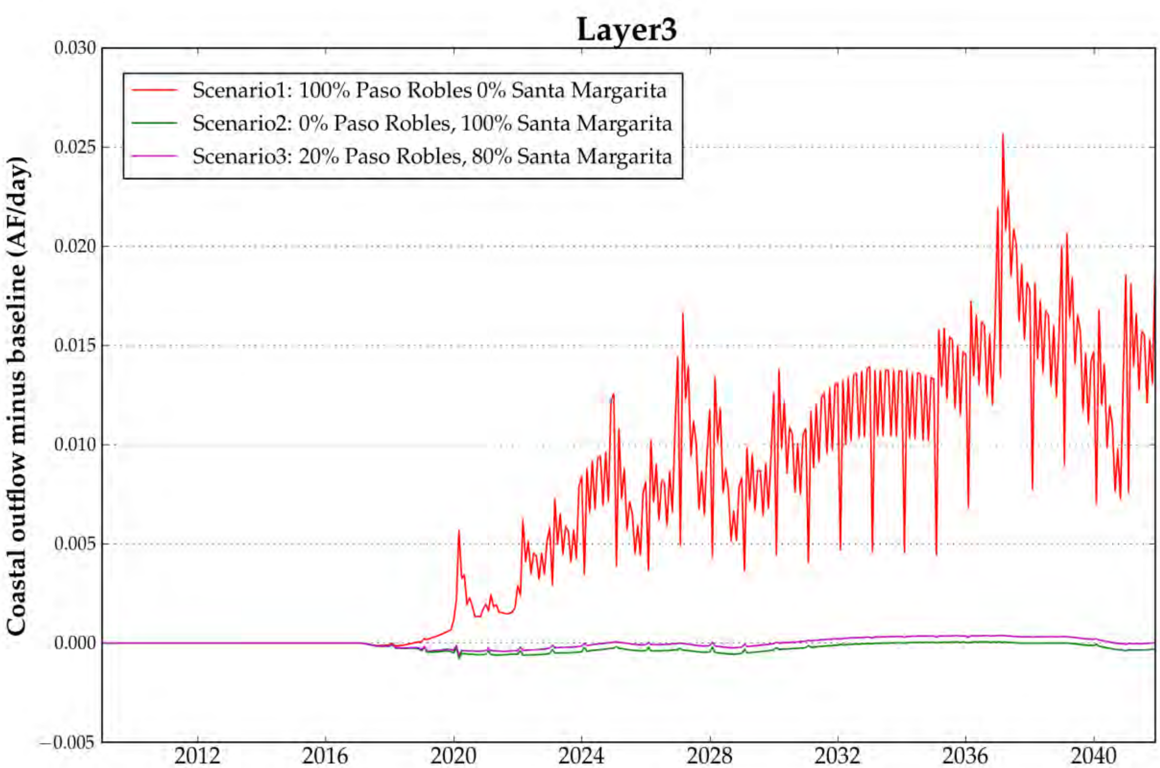

**Figure 2: Coastal Outflow along Layer 3 General Head Boundary**

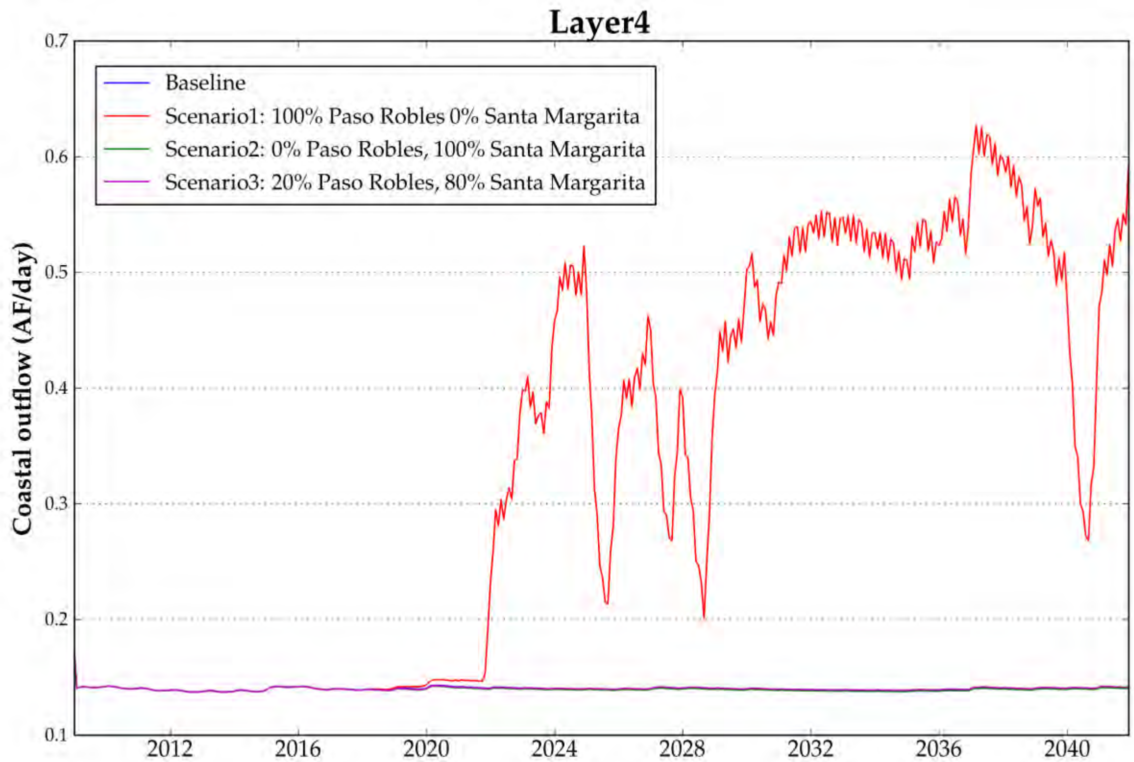

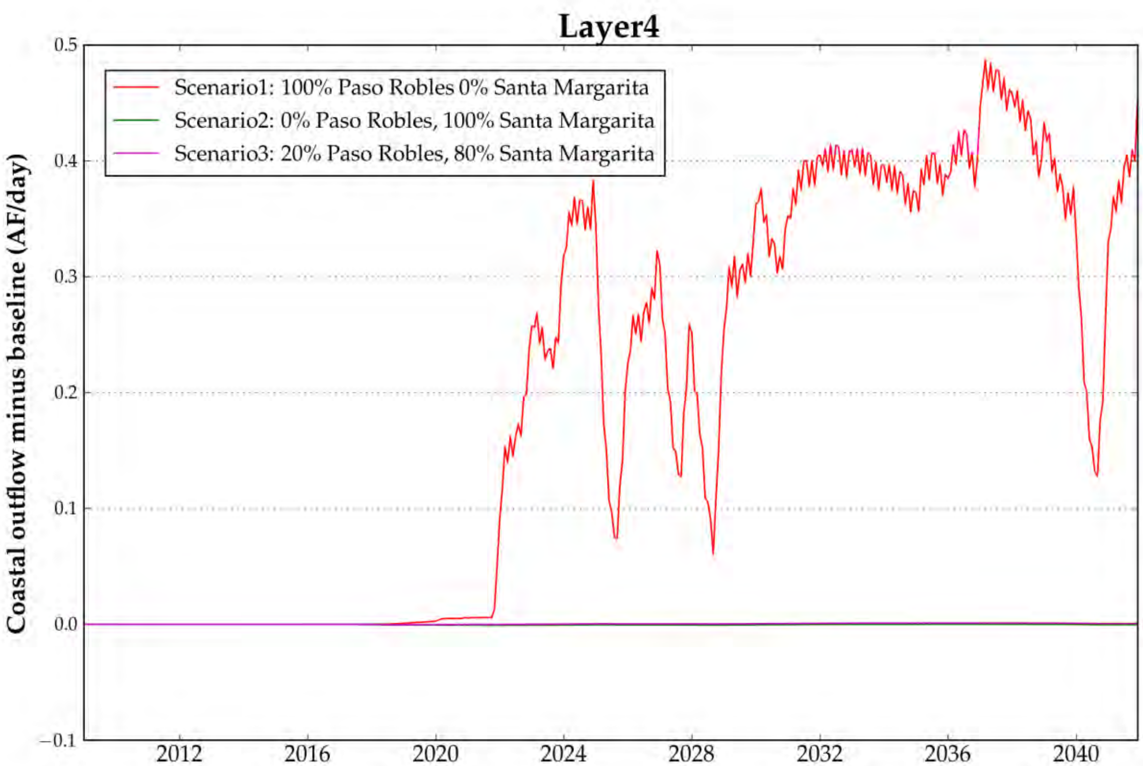

**Figure 3: Coastal Outflow along Layer 4 General Head Boundary**

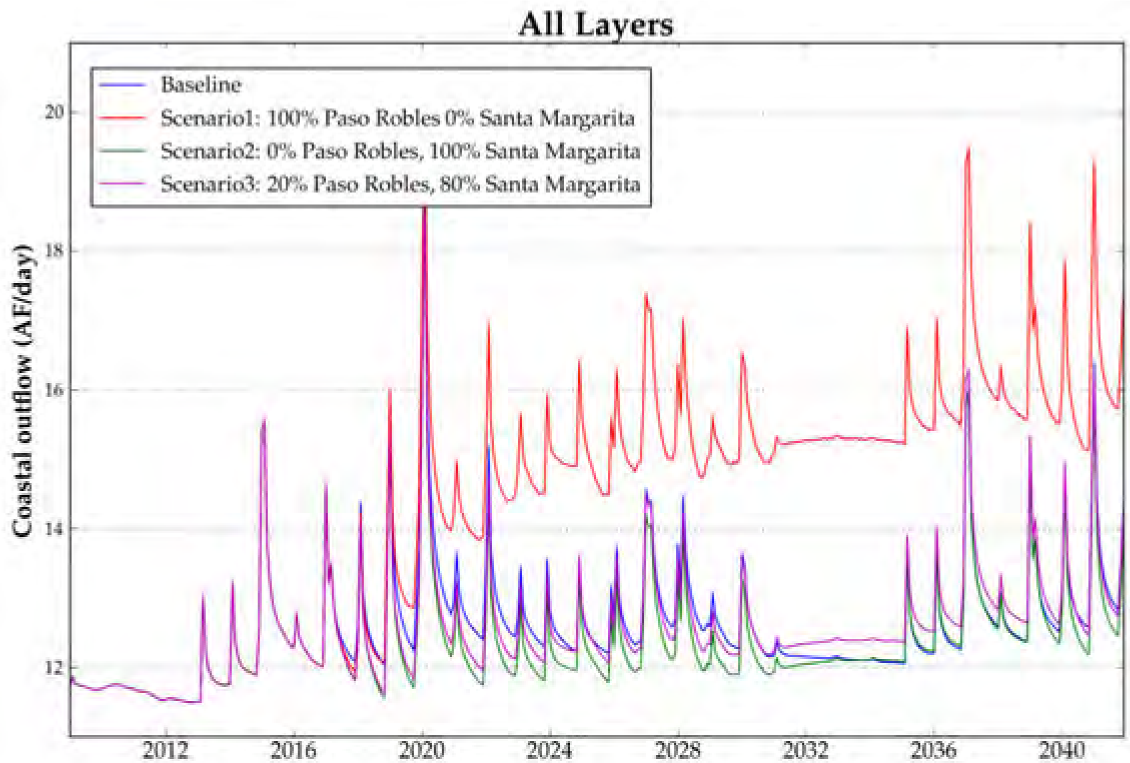

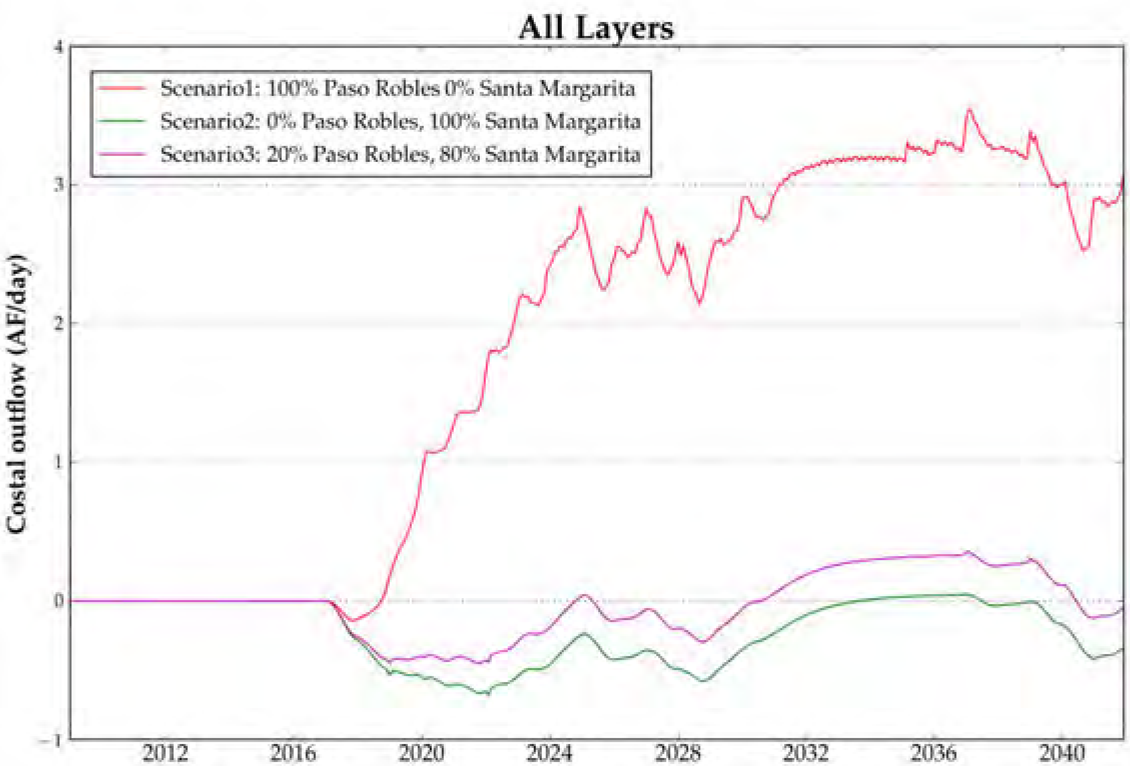

**Figure 4: Coastal Outflow along Layers 1-4 General Head Boundaries**

**Storage Changes Criterion**

The change in the amount of water stored in the basin under each simulation was a second criterion for assessing the impact caused by GWR recharge. A basin in which inflows and outflows are balanced over time will have no average change in storage (at the same time that it will have stable water levels). The inflows and outflows of the Seaside Basin are not currently balanced, but as stated above, it is not the goal of the GWR project to change the water balance. As with the outflow criterion, the changes in storage for each scenario were compared to those of the baseline to assess the performance of each scenario, with the smallest difference indicating the least impact.

Table 2 shows the total volumetric changes in storage, with positive numbers indicating increases in the amount of water in storage and negative numbers indicating decreases in the amount of water in storage. The imbalance present in scenario 1 between the shallow layers that are recharged and the deep layers that are preferably pumped can be plainly seen. Under this scenario there is a large increase in storage in the shallow layers and a large decrease in storage in deep layer 5. These results show that the largest changes occur within the adjudicated basin, but that there are also differences in the storage occurring outside of the adjudicated basin. This indicates that changes in flow are taking place along the inland boundaries and not just the coastal boundary. This was not investigated further.

Table 3 shows the difference in the volumetric storage changes for each scenario compared to the baseline, and Table 4 expresses these as a percent of the total volume of GWR water. Positive values indicate that a scenario has more water in storage than baseline conditions and negative values indicate that a scenario has less water in storage than baseline conditions. These results indicate that scenarios 2 and 3 do a much better than scenario 1 at minimizing changes in the basin relative to the baseline. Each scenario shows changes in storage that only a few percent of the total water recharged (and extracted) with the GWR project. Scenario 2 appears better if the scope is limited to the adjudicated basin while scenario 3 appears better if the entire model region is considered.

### Table 2: Total Change in Storage (AF)

| Scenario | Adjudicated Basin | | | | | | Outside of Adjudicated | Entire Model |
|---|---|---|---|---|---|---|---|---|
| | Layer1 | Layer2 | Layer3 | Layer4 | Layer5 | All Layers | | |
| Baseline | 1,794 | 95 | -198 | -858 | -3,738 | -2,905 | -35,079 | -37,984 |
| Scenario1 | 2,895 | 19,406 | 5,871 | 3,664 | -15,626 | 16,211 | -49,993 | -33,782 |
| Scenario2 | 1,697 | -78 | -17 | -824 | -1,528 | -749 | -32,498 | -33,247 |
| Scenario3 | 1,772 | 2,651 | 786 | -364 | -4,723 | 121 | -36,811 | -36,690 |

+ : More into Storage (higher water levels/ pressure)

- : Less into Storage (lower water levels/ pressure)

### Table 3: Difference from Baseline

| Scenario | Adjudicated Basin | | | | | | Outside of Adjudicated | Entire Model |
|---|---|---|---|---|---|---|---|---|
| | Layer1 | Layer2 | Layer3 | Layer4 | Layer5 | All Layers | | |
| Scenario1 | 1,102 | 19,311 | 6,070 | 4,523 | -11,889 | 19,116 | -14,914 | 4,202 |
| Scenario2 | -97 | -173 | 182 | 34 | 2,210 | 2,156 | 2,581 | 4,737 |
| Scenario3 | -22 | 2,556 | 984 | 495 | -986 | 3,026 | -1,732 | 1,294 |

+ : More into Storage (higher water levels/ pressure)

- : Less into Storage (lower water levels/ pressure)

### Table 4: Difference from Baseline as Percent of Total Recharged Water (AF)

| Scenario | Adjudicated Basin | | | | | | Outside of Adjudicated | Entire Model |
|---|---|---|---|---|---|---|---|---|
| | Layer1 | Layer2 | Layer3 | Layer4 | Layer5 | All Layers | | |
| Scenario1 | 1.2% | 21.8% | 6.9% | 5.1% | -13.5% | 21.6% | -16.9% | 4.8% |
| Scenario2 | -0.1% | -0.2% | 0.2% | 0.0% | 2.5% | 2.4% | 2.9% | 5.4% |
| Scenario3 | 0.0% | 2.9% | 1.1% | 0.6% | -1.1% | 3.4% | -2.0% | 1.5% |

+ : More into Storage (higher water levels/ pressure)

- : Less into Storage (lower water levels/ pressure)

## Conclusion

These analyses suggest that recharging between 80% and 100% of GWR water into the Santa Margarita formation through deep injection wells will result in minimal disturbance to the basin and to only small amounts of water being lost to outflow from basin. These results are consistent with the idea that the water should be delivered into the same formations from which water is drawn.

If you have any questions, do not hesitate to contact me.

Sincerely,

Derrik Williams

Derrik Williams, President
HydroMetrics Water Resources Inc.

## HydroMetrics Technical Memorandum

## GWR Project EIR: Project Modeling Results, January 12, 2015

1814 Franklin St, Suite 501
Oakland, CA 94612

# TECHNICAL MEMORANDUM

To: Bob Holden/MRWPCA

From: Stephen Hundt and
Derrik Williams

Date: January 12, 2015

Subject: GWR Project EIR: Project Modeling Results

## Executive Summary

The Monterey Regional Water Pollution Control Agency (MRWPCA) is developing a Groundwater Replenishment (GWR) project for the Seaside Basin. This project will recharge the Seaside groundwater basin with high quality purified water. The current analysis seeks to assess the environmental impacts of operating the GWR project, in fulfillment of the GWR project's Environmental Impact Report (EIR) requirement.

The calibrated groundwater model of the Seaside Groundwater Basin (HydroMetrics WRI, 2009) was used to estimate impacts from the GWR Project. A predictive model incorporating reasonable future hydrologic conditions was developed for this impact analysis. The groundwater model was calibrated through 2008; therefore the predictive model begins in 2009. The predictive model simulates a 33 year period: from 2009 through 2041.

Simulated future Carmel River flows were based on historical flow records. The amount of Carmel River water available for winter injection into the Seaside Basin was estimated by Monterey Peninsula Water Management District (MPWMD) staff. They compared historical daily streamflows with minimum streamflow requirements for each day, and then identified how much water could be extracted from the Carmel River for injection each month.

Future water demand for Cal-Am was estimated from historical demands for the period 2001-2010. Roughly two-thirds of the total Cal-Am demand was predicted to be met by extraction of native groundwater, injected Carmel River water, and injected GWR water. The monthly pumping rate within each year was distributed in proportion to the total monthly demand, with modifications made to compensate for capacity reductions caused by ASR injection.

Model results show that the GWR project is generally neutral compared to the no project conditions. Groundwater elevations are generally similar under the project conditions as under the no project conditions, with increasing groundwater elevations experienced under both scenarios. These higher groundwater levels will tend to slow or stop seawater intrusion.

Particle tracking was used to estimate the travel time of GWR water from the point of recharge to the closest point of extraction. Particle tracking showed that the shortest travel time for any recharged GWR water is about 11 months. Travel times of less than 12 months occur in 5 years out of the 25-year simulation period when the GWR project is in operation.

# Project Description

The Monterey Regional Water Pollution Control Agency (MRWPCA) is developing a Groundwater Replenishment (GWR) project for the Seaside Basin. This project will recharge the Seaside groundwater basin with high quality purified water and deliver lesser quality recycled water to the Castroville Seawater Intrusion Project (CSIP). California American Water Company (Cal-Am) will recover 3,500 AFY of the recharged water through existing production wells in the basin, based on demand and well capacity/availability. The project will also include a groundwater banking program that will build a drought reserve account of up to 1,000 AF of water in the Seaside Basin during normal and wet years. The extra recharge during normal and wet years will be offset by an increase in CSIP deliveries and a corresponding decrease in Seaside groundwater basin injection during dry years when water is in the reserve account. The locations of the project's facilities, along with other operating production wells, are shown on Figure 1.

HydroMetrics Water Resources Inc. (WRI) has completed groundwater flow and particle tracking simulations of the proposed GWR project. This simulation was undertaken to predict impacts on groundwater levels and the fate and travel time of injected GWR water. This modeling was completed in support of the GWR project's environmental impact report (EIR).

*Figure 1: Production and GWR Injection Well Locations*

# Model Background and Assumptions

The calibrated groundwater model of the Seaside Groundwater Basin (HydroMetrics WRI, 2009) was used to estimate the impacts from the GWR Project. A predictive model incorporating reasonable future hydrologic conditions was developed for this impact analysis. The groundwater model was calibrated through 2008; therefore the predictive model begins in 2009. The predictive model simulates a 33 year period: from 2009 through 2041. The GWR project was assumed to start in October 2016 and was operating throughout the remaining 25 years of the simulation. Recent estimates indicate that the project start-up may be delayed until late 2017, but the project was simulated with the previous start date to provide an additional year of analysis.

## PREDICTED HYDROLOGY ASSUMPTIONS

The hydrology (rainfall and recharge) used to calibrate the groundwater model was applied to the predictive model. To extend the hydrology through the predictive period, the 1987 through 2008 hydrology data were used to simulate model years 2009 through 2030, and the 1987 through 1997 hydrology data were then repeated for 2031 through 2041 (Figure 2). This is the approach that has been adopted for all predictive models of the Seaside Basin since 2009. By using this hydrology, even during the period January 2009 to present when actual hydrology is known, the model runs can be used to compare relative groundwater levels but not to assess absolute Basin conditions.

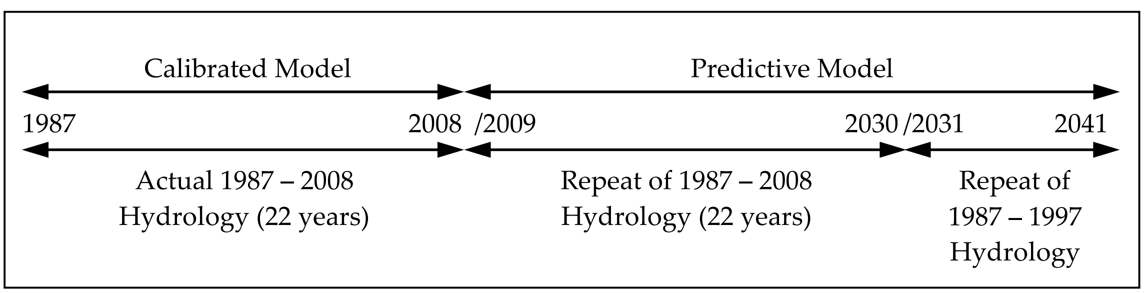

*Figure 2: Repetition of Hydrology for Predictive Model*

## PREDICTED CARMEL RIVER FLOW AND INJECTION ASSUMPTIONS

Monterey Peninsula Water Management District (MPWMD) estimated the amount of Carmel River water available for ASR injection for the predictive simulation based on historical streamflow records. Because the future simulated hydrology is based on the historical hydrology between 1987 and 2008, the future streamflows are expected to be the same as the historical streamflows. MPWMD staff compared historical daily streamflows between water year 1987 and water year 2008 with minimum streamflow requirements for each day. This allowed MPWMD to identify how many days in each month ASR water could be extracted from the Carmel River. Using a daily diversion rate of 20 acre-feet per day, MPWMD calculated how many acre-feet of water from the Carmel River could be injected into the ASR system each month. Figure 3 shows the estimated available monthly ASR injection volumes for the predictive simulation. Appendix A includes the historic and projected ASR Wells Site injection schedule that was developed by MPWMD. The Carmel River water available for injection was divided between the ASR 1&2 Well Site and the ASR 3&4 Well Site according to the historic division.

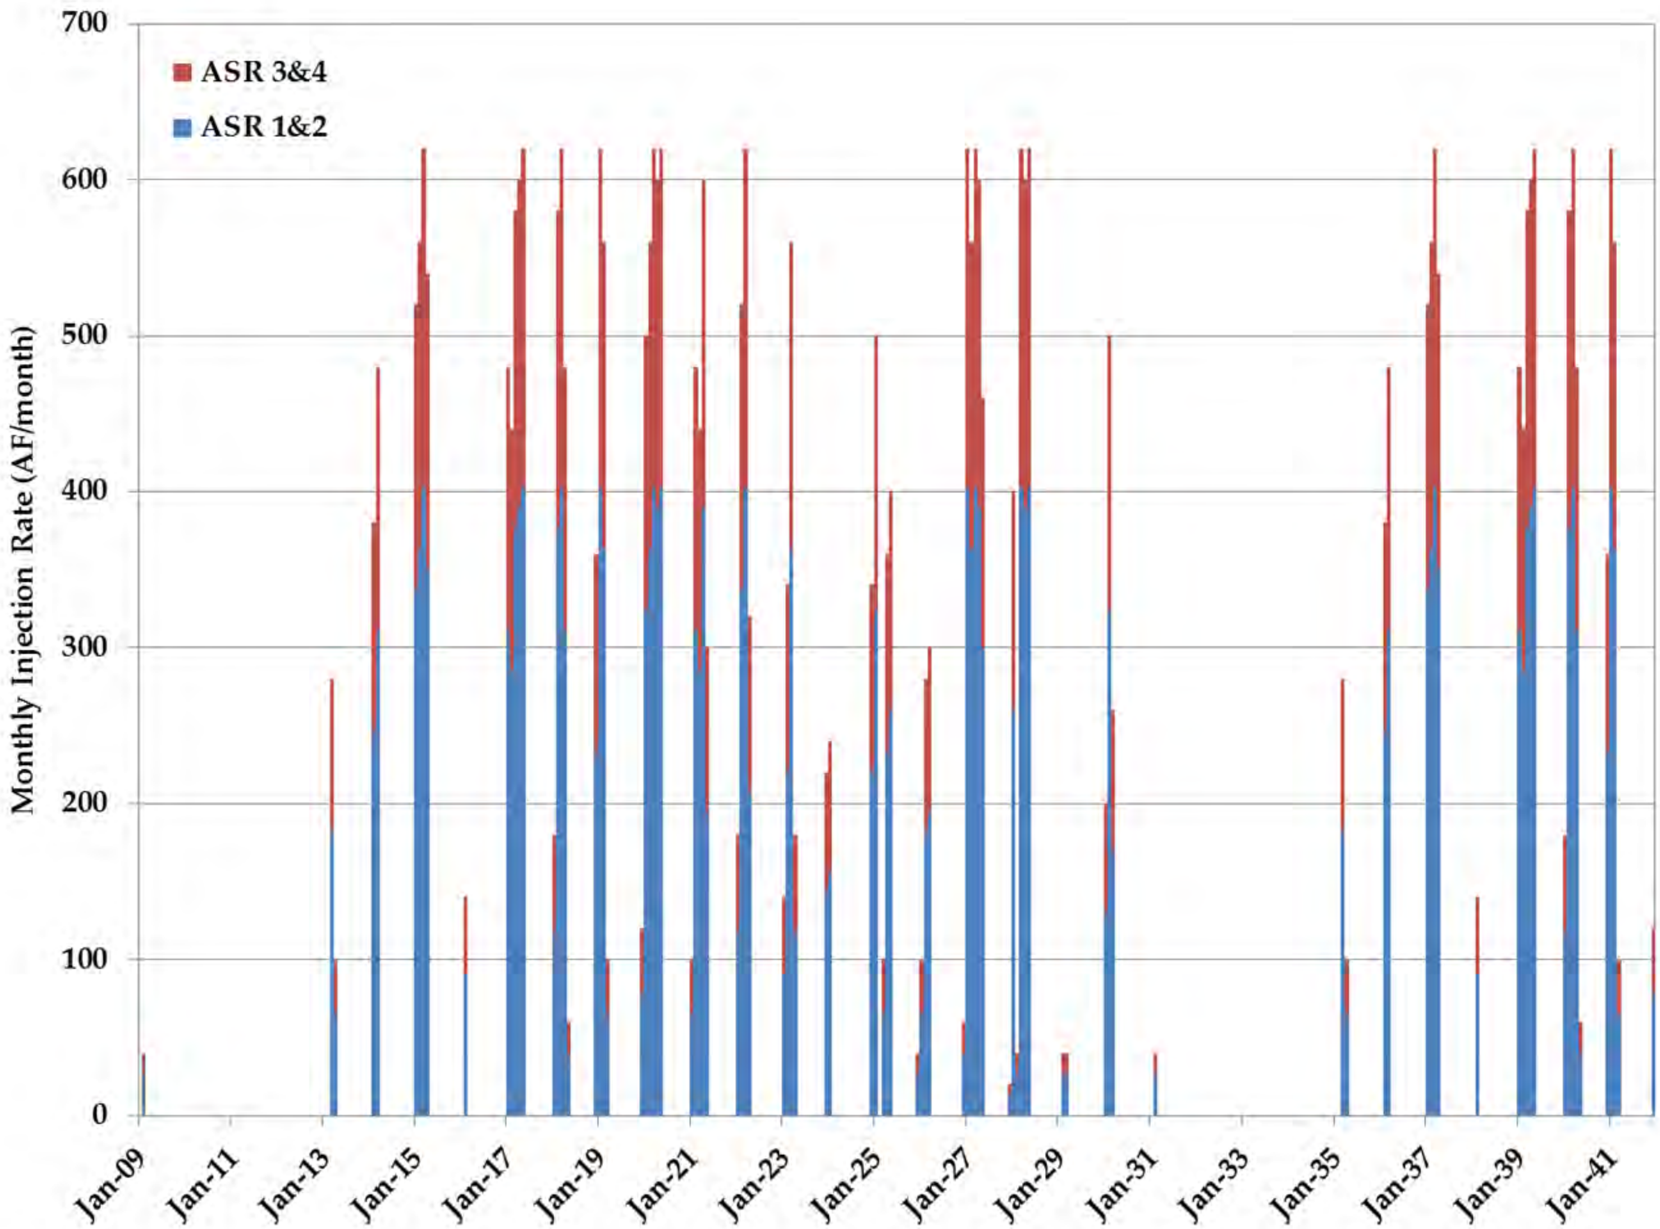

*Figure 3: Estimated Monthly Carmel River ASR Injection Volumes*

## PREDICTED GWR RECHARGE ASSUMPTIONS

GWR Project water is recharged through four deep wells and four vadose zone wells in the predictive model. The simulated GWR project recharges varying volumes of water each year, with an average of 3500 acre-feet recharged per year. Of this, 90% of the water is delivered to the Santa Margarita aquifer through four deep injection wells, and the remaining 10% is delivered to the Paso Robles aquifer through four vadose zone well. The amount of water recharged each year depends upon whether the predicted hydrology is in a drought or non-drought year, and upon the rules for banking and delivering water to CSIP. Figure 4 shows the volume of water recharged by the GWR project for each water year. While the annual recharge of GWR water varies from year to year, the recovery of water through Cal-Am's pumping wells is maintained at a constant 3500 acre-feet every year. A monthly recharge schedule that includes an accounting and description of the CSIP banking and delivery program is shown on the 11 x 17 sized table at the end of this technical memorandum.

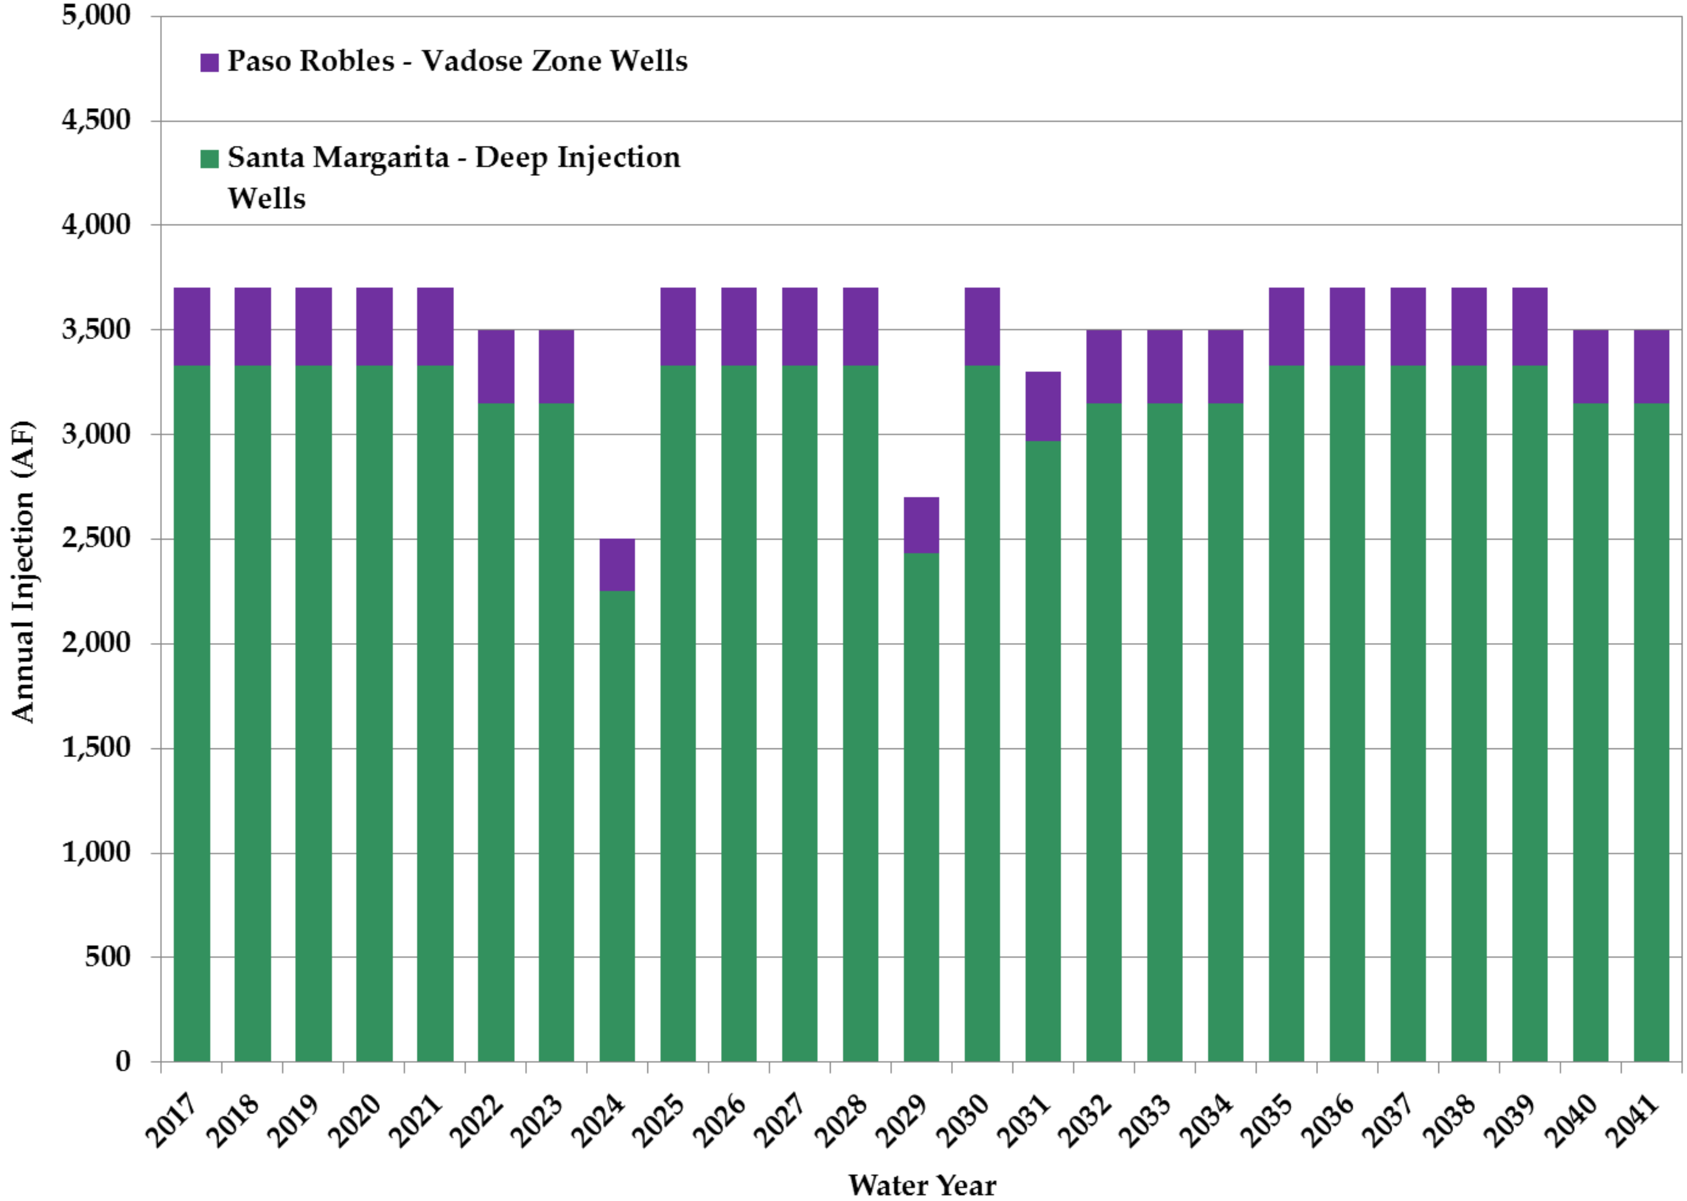

*Figure 4: Annual GWR Recharge*

## PREDICTED PUMPING ASSUMPTIONS

HydroMetrics WRI made a number of assumptions about future pumping rates by various entities in the Seaside Basin. These assumptions were consistent with assumptions developed for previous modeling exercises in the basin. Pumping assumptions were developed for standard producers, alternative producers, golf courses, and Cal-Am.

### WATER YEAR 2009 THROUGH WATER YEAR 2012 PUMPING

Actual pumping and injection data for all wells from January 2009 through December 2012 are included in the predictive simulation.

### MUNICIPAL PUPMPING FROM WATER YEAR 2013 ONWARDS

Predicted pumping by the City of Seaside and the City of Sand City follows the triennial reductions prescribed in the Amended Decision (California American Water v. City of Seaside et al., 2007). These pumping reductions are designed to reduce basin-wide pumping to the approximate safe yield of 3,000 acre-feet per year by 2021.

### CAL-AM PUMPING FROM WATER 2013 ONWARDS

A number of assumptions were necessary to estimate Cal-Am's monthly pumping rates and pumping distribution. Assumptions about Cal-Am's future pumping constraints and future demands are discussed below.

#### Cal-Am Pumping Constraints

Predicted Cal-Am pumping comes from the five existing Cal–Am wells, and two ASR sites. The five existing Cal-Am wells are:

- Luzern #2
- Ord Grove #2
- Paralta
- Playa #3
- Plumas #4

Data supplied by Cal-Am show that the pumping capacity of their five existing wells is 3,653 gallons per minute, or 16 acre-feet per day. Based on conversations with the Monterey Peninsula Water Management District (MPWMD), we assumed that each

ASR well site could produce 1,750 gallons per minute. The total pumping capacity of all seven wells is therefore 7,153 gallons per minute, or 31.6 acre-feet per day.

Information from MPWMD helped determine when ASR wells are unavailable for pumping. MPWMD developed the future injection and extraction schedule of the ASR wells based upon their historical monthly operation from October 1986 to 2008. This historical timeframe aligns with the observed climate and hydrologic pattern that are used to specify the future climate and hydrologic pattern in the groundwater model. The MPWMD injection and extraction schedule identifies months when ASR wells are not available to pump groundwater, either because they are being used for injection or they are resting. For months when the ASR wells were not available, Cal-Am's pumping capacity was set to 16.1 acre-feet per day. For months when the ASR wells were available, Cal-Am's pumping capacity was set to 31.6 acre-feet per day.

**Cal-Am Water Demand**

The monthly distribution of Cal-Am's total water demand was used to estimate a likely monthly distribution of future pumping. The total demand from Cal-Am customers in the Seaside Basin is currently supplied from a variety of sources. Groundwater pumping may become a more significant source of Cal-Am's supply in the future. Cal-Am's historical demand numbers were provided by MPWMD. The values are based on average water deliveries for the years 2001-2010.

Table 1 shows the calculations used to estimate Cal-Am's future monthly pumping demand. The current average monthly demand, shown in acre-feet in the second column, is the measured demand provided by MPWMD. It is worth noting that the maximum monthly demand of 1,490 acre-feet (48 acre-feet per day) far exceeds the assumed combined well capacity of about 31.6 acre-feet per day.

The third column shows the percentage of Cal-Am's demand by month. We assumed that the maximum demand month of July represents a time when Cal-Am is pumping at its full capacity of 31.6 acre-feet per day. The demand for each other month, shown in column 4, was scaled as a percentage of this full capacity. For example, we calculated that Cal-Am only pumps 64% of its capacity in March, because the March demand is only 64% of the July demand. Column 5 shows the amount of water Cal-Am would likely pump in any month. Column 5 values are calculated by multiplying the percentages in column 4 by the full pumping capacity of 31.6 acre-feet per day.

*Table 1: Cal-Am Estimated Seasonal Demand*

| Month | Cal-Am Current Average Monthly Demand (AF) | Percent of Annual Production | Percent of July Production | Estimated Future Monthly Pumping (AF) |
|---|---|---|---|---|
| October | 1242 | 8.96% | 0.83 | 816 |
| November | 1005 | 7.25% | 0.67 | 660 |
| December | 900 | 6.49% | 0.60 | 591 |
| January | 871 | 6.28% | 0.58 | 572 |
| February | 814 | 5.87% | 0.55 | 534 |
| March | 947 | 6.83% | 0.64 | 622 |
| April | 1049 | 7.57% | 0.70 | 689 |
| May | 1307 | 9.43% | 0.88 | 858 |
| June | 1400 | 10.10% | 0.94 | 919 |
| July | 1490 | 10.75% | 1.00 | 978 |
| August | 1469 | 10.60% | 0.99 | 965 |
| September | 1363 | 9.84% | 0.92 | 895 |

Based on these calculations, Cal-Am's total future annual pumping demand is 9,099 acre-feet per year.

**Annual water available for Cal-Am pumping**

Cal-Am's future pumping from the Seaside basin will be drawn from three pools of water:

- Native groundwater
- Groundwater replenishment (GWR) project water
- Aquifer storage and recovery (ASR) project water

The availability of these resources is graphed on Figure 5. This graph consists of the three components listed above.

- The native water (red) is subject to triennial reductions through 2021. After 2021, the amount of pumping native water is held constant. This pool of water also includes pumping for Security National Guaranty, Inc. (SNG, a groundwater pumper) development which increases from 2013 through 2017.

- GWR water (green) is projected to become available in 2017, and supply 3500 acre-feet every year.
- ASR water (blue) availability is subject to weather conditions. The maximum amount that can be pumped annually is 1,500 acre-feet. Less is pumped during dry years.

The dashed purple line on Figure 5 is Cal-Am's estimated total future annual pumping demand of 9,099 acre-feet per year. The water available for pumping from the three pools of water is projected to be less than the pumping demand for all years. The dashed orange line is the annual demand that Cal-Am could reasonably pump, given the reductions in capacity that take place when the ASR wells are unavailable for extraction.

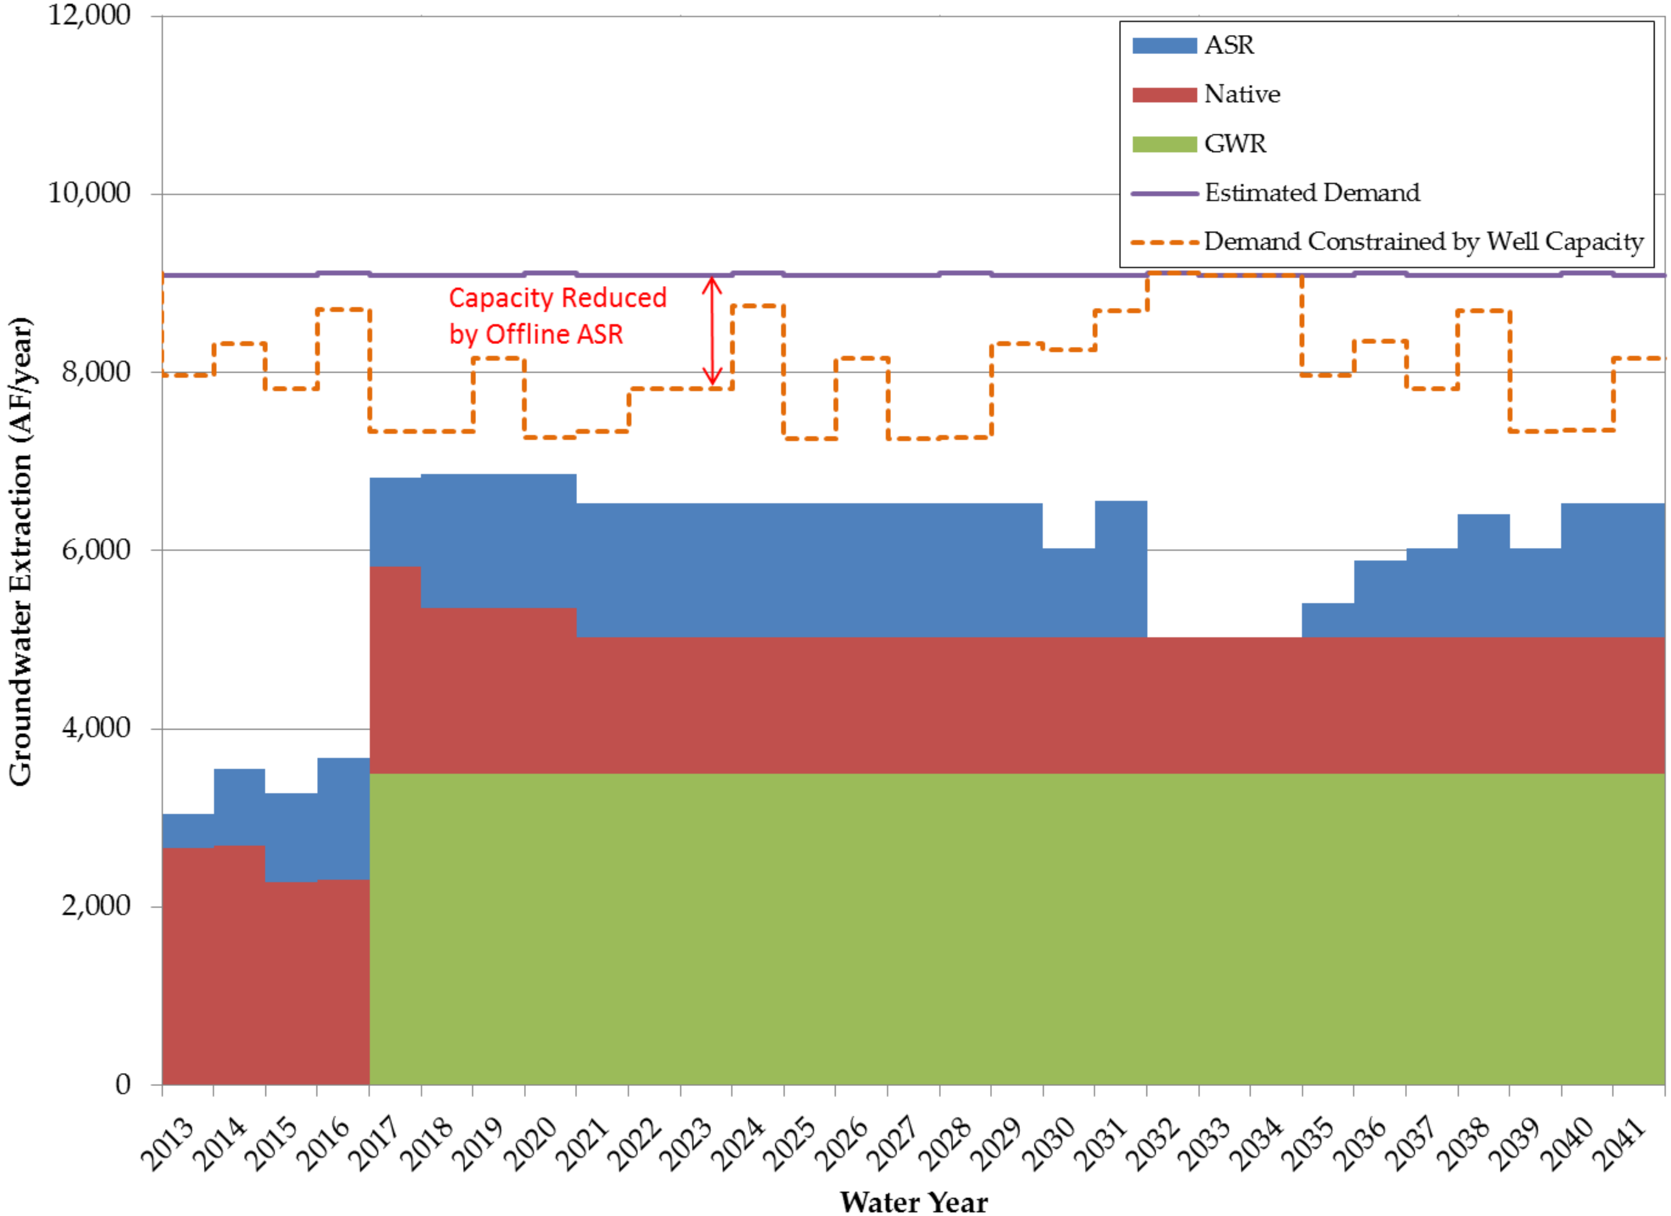

*Figure 5: Annual Cal-Am Water Allocation by Water Right Source*

**Pumping Allocation by Well**

When no ASR water is being extracted, Cal-Am's monthly pumping from the Seaside Basin is allocated among their available wells with the following order of preference:

- Ord Grove #2
- Paralta
- ASR wells
- Luzern
- Playa #3
- Plumas #4

The total demand during any month was first allocated to the Ord Grove Well up to its capacity. Demand was then allocated to the Paralta Well up to its capacity, and so on. The ASR wells are considered unavailable for extraction if they are injecting water, or have injected water at any time during the previous 3 months. The projected injection schedule was used to flag months during which the ASR wells would be unavailable. During months when ASR wells are not available for pumping, the order of preference continues directly from the Paralta Well to the Luzern well. This generally occurs during early summer, when total pumping is high and the ASR has recently injected excess spring rainfall. Figure 6 shows the monthly pumping by well.

When ASR water is being extracted, the ASR wells are preferentially used to extract ASR water. If the ASR wells' capacity is inadequate to extract all ASR water, the remaining ASR water is allocated to the remaining wells as described above. If the ASR wells' capacity is greater than the ASR water allocated during a month, then the ASR wells remain available to extract native and GWR water up to their remaining capacity.

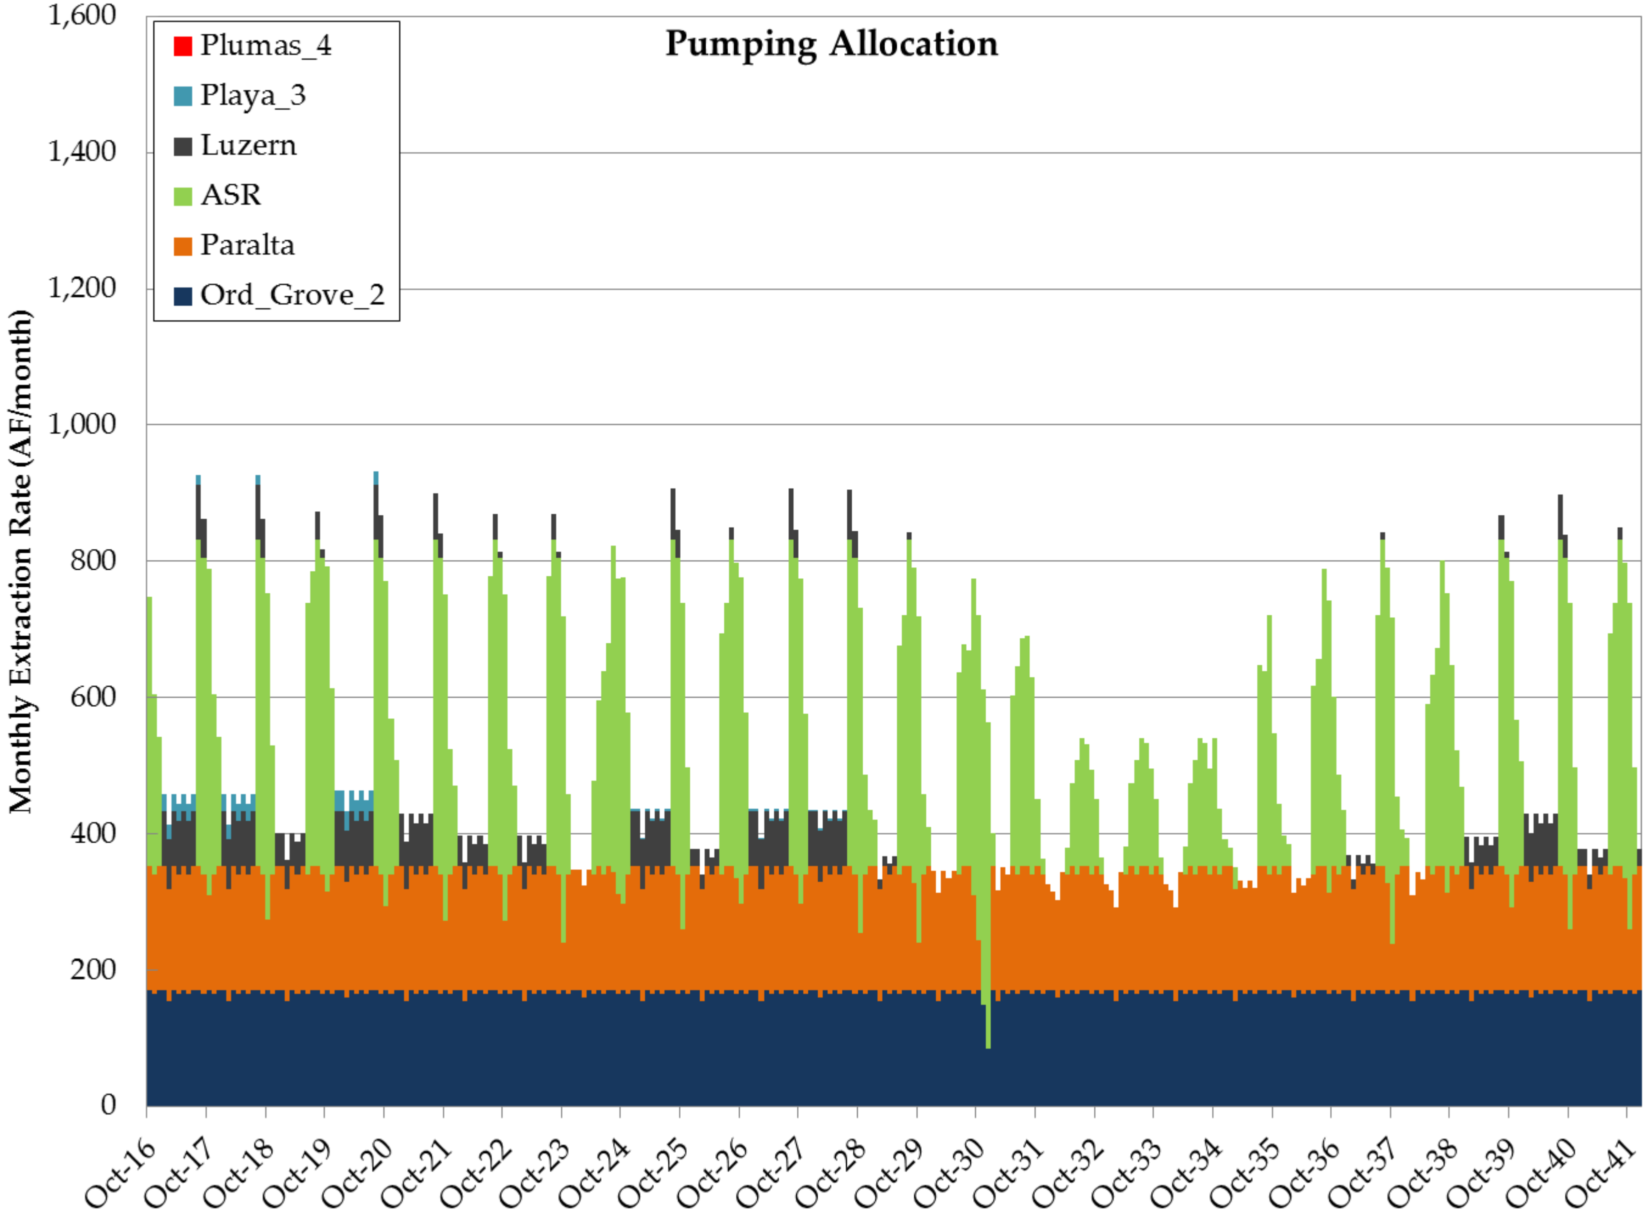

*Figure 6: Monthly Pumping Totals by Well*

## GOLF COURSE PUMPING FROM WATER YEAR 2013 ONWARDS

Predicted golf course pumping is based on the hydrologic year. For example, pumping in January 2015 equals the amount pumped in January 1993, because the simulated 2015 hydrology is based on 1993 hydrology. This ensures that the demand corresponds to the hydrology. If the amount pumped by a Producer pre-adjudication exceeded the Producer's adjudicated right, pumping was capped at the Producer's adjudicated amount.

Additional golf course pumping adjustments accounted for in the simulation are:

- The Bayonet and Blackhorse golf courses pump no water until September, 2016. This is based on an in-lieu replenishment program the City of Seaside has with its golf course pumping. Under this program, Marina Coast Water District provides water in-lieu of the City pumping from the Seaside Basin. The City expects to start pumping its golf course wells again starting September 2016.

- In 2007, Bayonet and Black Horse golf courses had irrigation upgrades that have reduced irrigation demand by approximately 10% from historical amounts.

- The City of Seaside expects to begin pumping an average of 360 AFY from its wells for golf course supply starting in September 2016. These projected quantities were used rather than basing demand on the hydrology year.

## PREDICTED ALTERNATIVE PRODUCER AND PRIVATE PUMPING

Predicted alternative producer pumping is set at measured Water Year (WY) 2011 volumes from WY 2013 onwards. All other pumpers that are not covered by the Decision, including Cal Water Service and private wells, also pump at WY 2011 volumes from WY 2013 onwards.

Pumping exceptions taken into account in the simulation are:

- Water for SNG, which is an Alternative Producer, is supplied from Cal-Am wells under an agreement with Cal-Am. When the SNG site is developed they will be supplied with water by Cal-Am, who will use SNG's water right of 149.7 acre-feet/year. Currently there is no production from the SNG well. Based on input from the property owner, Ed Ghandour, project construction is planned to start in 2013, and use 25 AFY of water. Water usage thereafter is estimated to be:

- 2014 -  30 AFY
- 2015 – 50 AFY
- 2016 onwards – 70 AFY

## No-Project Scenario

Prior to simulating impacts from GWR injection, a No-Project scenario was run to establish baseline conditions. The No-Project scenario included all of the assumptions on future hydrology, future ASR injection, future municipal pumping, and future alternative producer pumping discussed above. No GWR injection was included in the No-Project scenario.

Cal-Am pumping in the No-Project scenario was estimated using the same assumptions detailed above. The only difference is that no GWR water was available for extraction. The total annual amount of water pumped by Cal-Am is shown on Figure 7. The monthly pumping by well for the No-Project scenario is shown in Figure 8.

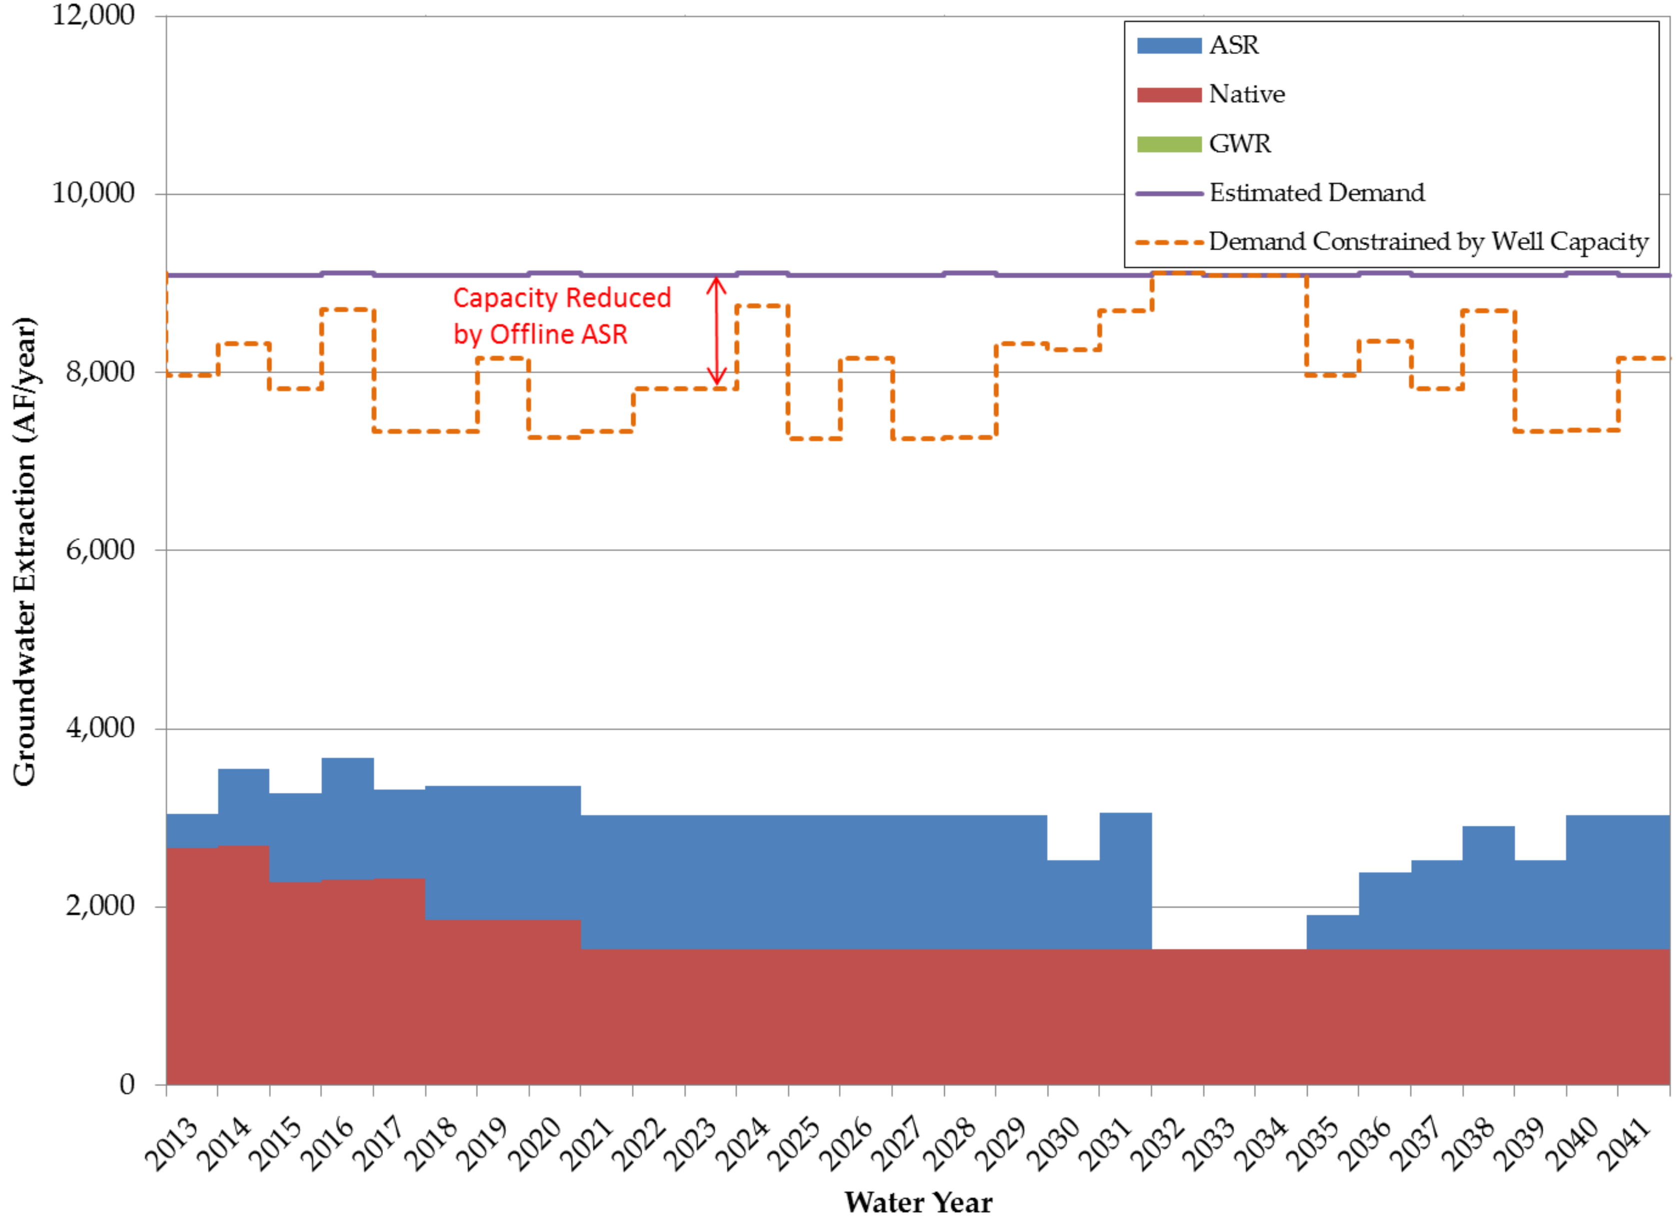

*Figure 7: Annual Cal-Am Water Allocation by Water Right Source for No-Project Scenario*

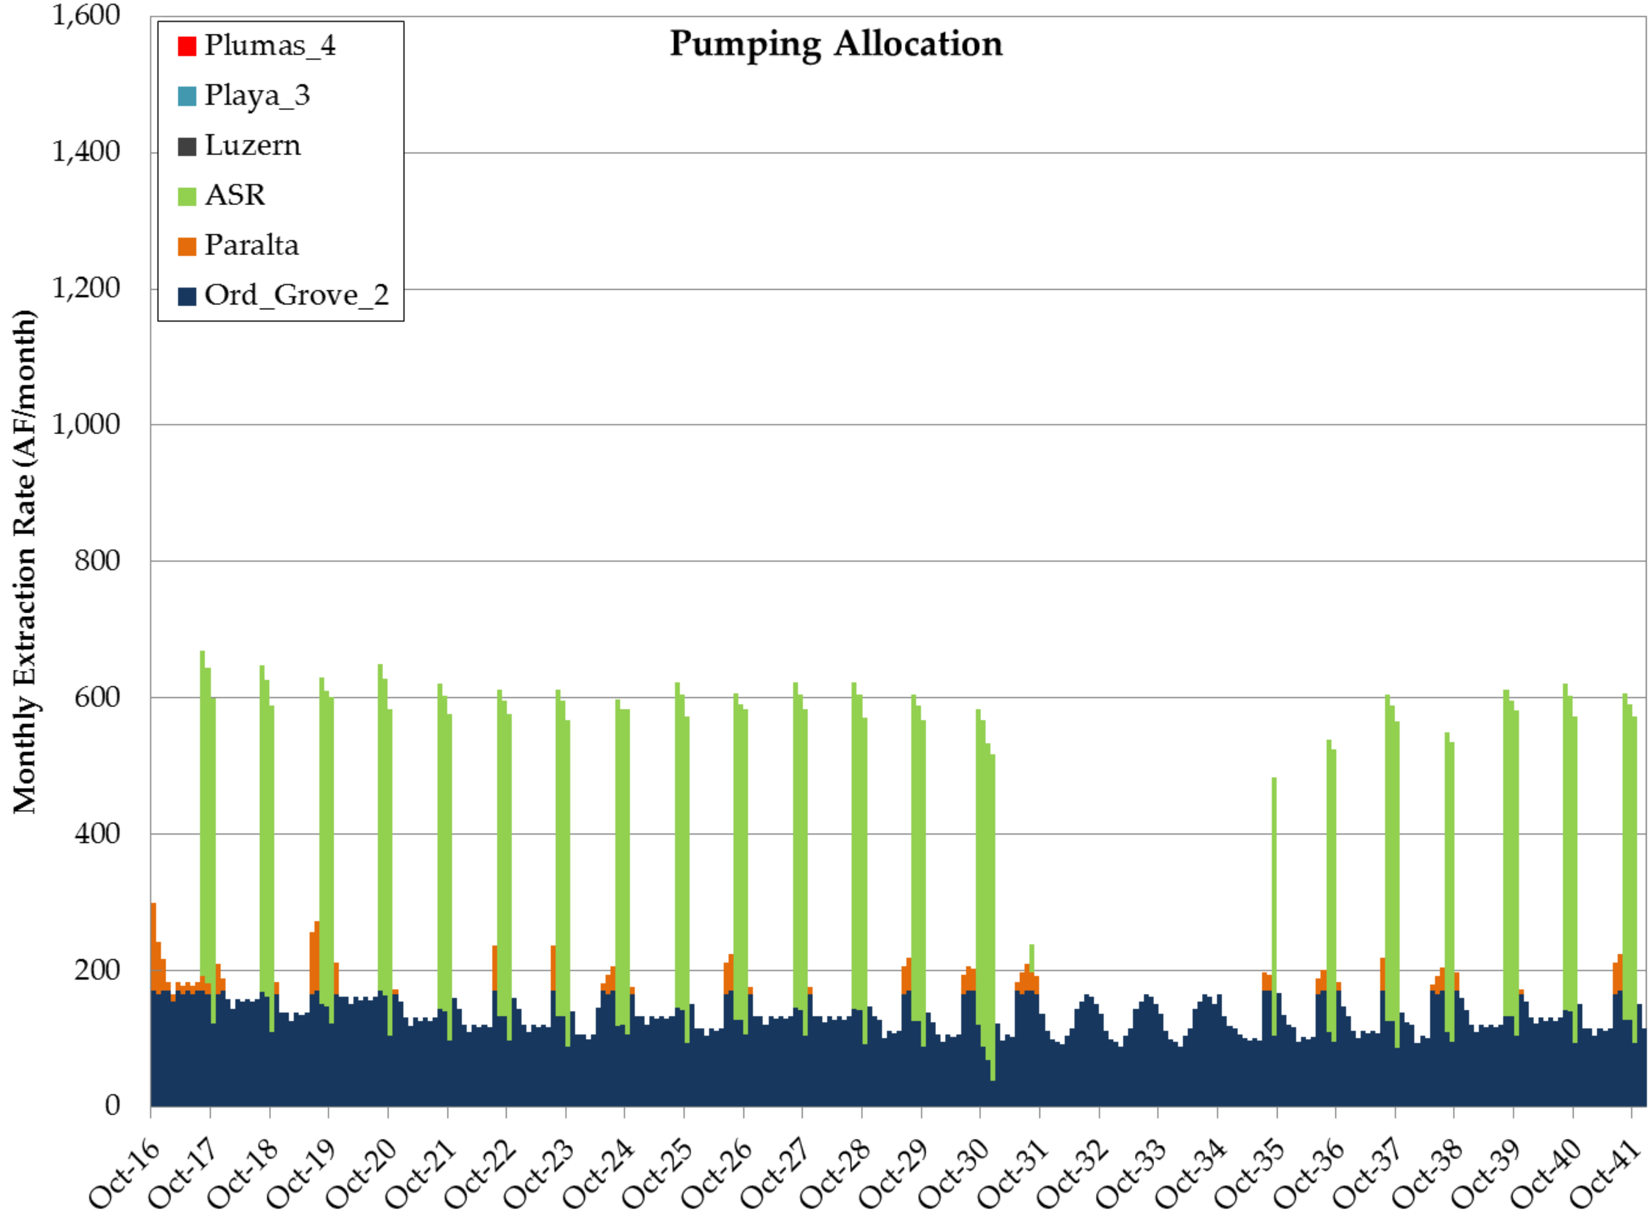

*Figure 8: Monthly Pumping Totals by Well for No-Project Scenario*

# Particle Tracking Approach

Particle tracking was conducted to estimate the fate and transport of GWR water under the Project Scenario. Particles were first introduced around all eight GWR Project injection wells on the simulated period corresponding to October 1, 2016. A new set of particles was released into the model at the beginning of every month until the end of the simulation in 2042. Each month, 40 particles were released from each injection well. Every particle was tracked through the model until it terminated at an extraction well, or until the end of the simulation period in 2042. By introducing the particles continuously, we ensured that there were particles introduced and tracked during times when the travel times would be the fastest.

Particles were placed along the edges of each of the model cells that contained the injection and vadose wells. This strategy is necessary to ensure that the particles are carried outward in all directions in the same manner that water would travel radially from a well. Placing many particles at the exact location of the well results in only a single path taken by all particles. While the approach of placing particles around the edge of the model cell gives a more accurate picture of the dispersal pattern of the water from the injection wells, it also places particles closer to the extraction wells, effectively resulting in faster simulated travel times.

Particles are captured by wells not when they reach the exact location of the extraction wells, but when they reach the edge of the cell that contains an extraction well. This also leads to faster simulated travel times. The results shown below should therefore be considered conservative estimates.

# Model Results

## GROUNDWATER ELEVATION RESULTS

The impact of the GWR project on groundwater elevations was determined by comparing results from the Project scenario with results from the No-Project scenario. The No-Project scenario simulates future groundwater conditions without the GWR project.

Simulated groundwater elevations from the three scenarios were compared at the following seven wells:

- ASR 1&2
- City of Seaside #3
- Ord Grove #2
- Paralta
- Luzern
- PCA-West (Shallow)
- PCA-West (Deep)

Figure 9 shows the location of these wells and the GWR injection wells. These wells span the area between the GWR injection wells and the coast. Several of the major recovery wells for the GWR project water are included in this set of wells.

Hydrographs for simulated groundwater elevations under the No-Project and Project scenarios are shown on Figure 10 through Figure 16. The blue lines represent the simulated static groundwater elevation under the No-Project scenario and the green lines represent the simulated static groundwater elevation under the with-Project scenario. Over the simulation period, the with-Project hydrographs deviate both below and above the No-Project hydrographs for several wells. The long term groundwater elevation trends of the with-Project hydrographs, however, are generally similar to the long-term trends of the No-Project hydrographs.

The largest relative reduction in groundwater levels under the with-Project scenarios are observed in the Ord Grove #2 well during the drought simulated between 2030 and 2035. During this period, the behaviors of the Ord Grove #2 hydrographs differ in several ways from the other deep wells: ASR wells #1 and #2, City of Seaside well #3, the Paralta well, and PCA-West Deep well. In all wells, there are large seasonal fluctuations throughout the simulation period that greatly diminish during the drought years. These drought year fluctuations tend to remain larger for the with-Project scenarios than for the No-Project scenarios and produce with-Project water levels that rise above No-Project water levels at their peak and fall below at their trough. In the Ord Grove #2 well, seasonal fluctuations under the with-Project scenario diminish during drought years, but not under the No-Project scenario. The with-Project groundwater elevations remain consistently lower than the No-Project groundwater elevations during the drought period.

There are several factors that control the seasonal fluctuations that occur in simulated groundwater elevations and help to explain the behavior of the Ord Grove #2 well hydrographs. First, the extraction and injection cycle of the ASR wells have a large impact on the seasonal cycles of nearby wells. ASR water is injected during the wet season, lifting groundwater elevations, and extracted during the dry season, dropping groundwater elevations. Injection and extraction of ASR water ceases entirely during the drought years leading to diminished fluctuations in groundwater elevations during these years.

For the with-Project scenarios, injection and extraction of GWR water does not cease, therefore with-Project scenarios experience greater groundwater level fluctuations than the no-Project scenario during the drought years. A second important factor controlling seasonal fluctuations are the seasonal pumping cycles of nearby (and coincident) production wells. Pumping tends to be heavier during the dry season, leading to declining water levels, and lighter during the wet season, leading to recovering water levels. This appears to be the most important factor causing the behavior seen in the Ord Grove #2 well. Figure 17 shows the pumping schedule of the Ord Grove #2 well for the No-Project and with-Project scenarios. While pumping fluctuates greatly under the No-Project scenario, the well is operated close to capacity during all months of the with-Project scenario. This general pattern continues during the drought period, with extended periods of light pumping during the winter months. This behavior compares closely to the Ord Grove #2 hydrographs, where the no-Project scenario sees greater fluctuations during the drought years than the with-Project scenarios. This helps to explain why the magnitude of fluctuations is higher in the Ord Grove #2 well, and why it appears to be much less sensitive to the ASR injection and extraction than its own pumping cycle.

The Luzern well and PCA-West Shallow well show relative reductions in groundwater elevations of one to six feet over the medium term of the simulations. At each of these wells the predicted groundwater elevations for the with-Project scenarios fall below the No-Project elevations soon after the GWR project comes online. Groundwater elevations then slowly recover to exceed or match the no-Project groundwater elevations by the end of the simulation. This behavior is likely a result of how the injection and additional pumping from the GWR project are distributed within the basin. The Luzern and PCA-West Shallow wells pump from the upper aquifers, not the Santa Margarita aquifer which receives most of the GWR injection. In the upper aquifer, the drop in groundwater elevation due to additional pumping from the Luzern and PCA-West Shallow wells is observed immediately. However the groundwater elevation rise due to both injection in the underlying aquifer and percolation of water through the upper aquifer is delayed. Wells screened in the underlying Santa Margarita aquifer do not show this delayed response because the pressure from GWR injection is transmitted quickly through the aquifer.

Comparing with-Project and No-Project Hydrographs of the PCA-West wells allows us to evaluate how the GWR project may impact seawater intrusion in the Seaside Basin. The simulated groundwater elevations at the PCA-West Deep well are very similar for the with-Project and No-Project scenarios, indicating that the GWR Project would not worsen the potential for seawater intrusion at this location. As previously discussed, hydrographs at the PCA-West Shallow well show relative reductions over the medium term for the Project Scenarios. While the initial relative decline is up to two feet, groundwater elevations remain above the predictive groundwater elevation for this location, and steadily rise to above four feet higher than protective elevations. Therefore, it does not appear that the GWR project would cause this location to become vulnerable to seawater intrusion.

## PARTICLE TRACKING RESULTS

Figure 18 shows how travel times between the GWR Project injection wells and the nearest extraction wells vary depending upon time of release. The horizontal axis represents the time at which groups of particles were released from the injection wells and the vertical axis represents time in days it took for the fastest particle to reach an extraction well. Each dot represents the time travelled by the fastest particle. The light blue, green, red, and dark blue dots show travel times from the locations of the deep injection wells DIW-1, DIW-2, DIW-3, and DIW-4, respectively. The black, yellow, orange, and magenta dots show travel times from the locations of the vadose zone wells VZW-1, VZW-2, VZW-3, and VZW-4, respectively.

The fastest particles are those released from well DIW-3, and captured at the ASR 1&2 Well Site. The fastest time any particle takes to travel from an injection well to a nearby extraction well is approximately 327 days. Travel times from deep injection well DIW-1 are the next fastest; taking approximately 724 days for the fastest particles to reach the ASR 3&4 Well Site. The fastest particles released at the remaining wells take between 2 and 14 years to reach an extraction well, with particles released from vadose zone well VZW-1 never reaching an extraction well after 24 years of simulation.

For most of the wells, there is a notable variation throughout the simulation in the minimum travel time taken by the released particles. For all four deep injection wells, the variations in travel times are strongly influenced by the ASR wells. These ASR wells both inject and extract water throughout the simulation period, thereby impacting groundwater gradients. These ASR wells sometimes draw particles in and sometimes repel them, creating greatly different trajectories depending on when a particle approaches the ASR wells. For example, particles that are released from well DIW-3 in the early winter and captured by wells ASR 1&2 in the late fall experience the fastest travel times. These particles approach the ASR 1&2 wells during the summer pumping season and are captured before any injection begins in the winter. Particles that approach the ASR wells during the simulated drought of 2030-2034 experience less seasonal variation in travel times. During this period, particles encounter no injection of Carmel River water that would repel them from their path and less pumping that to draw them toward a well.

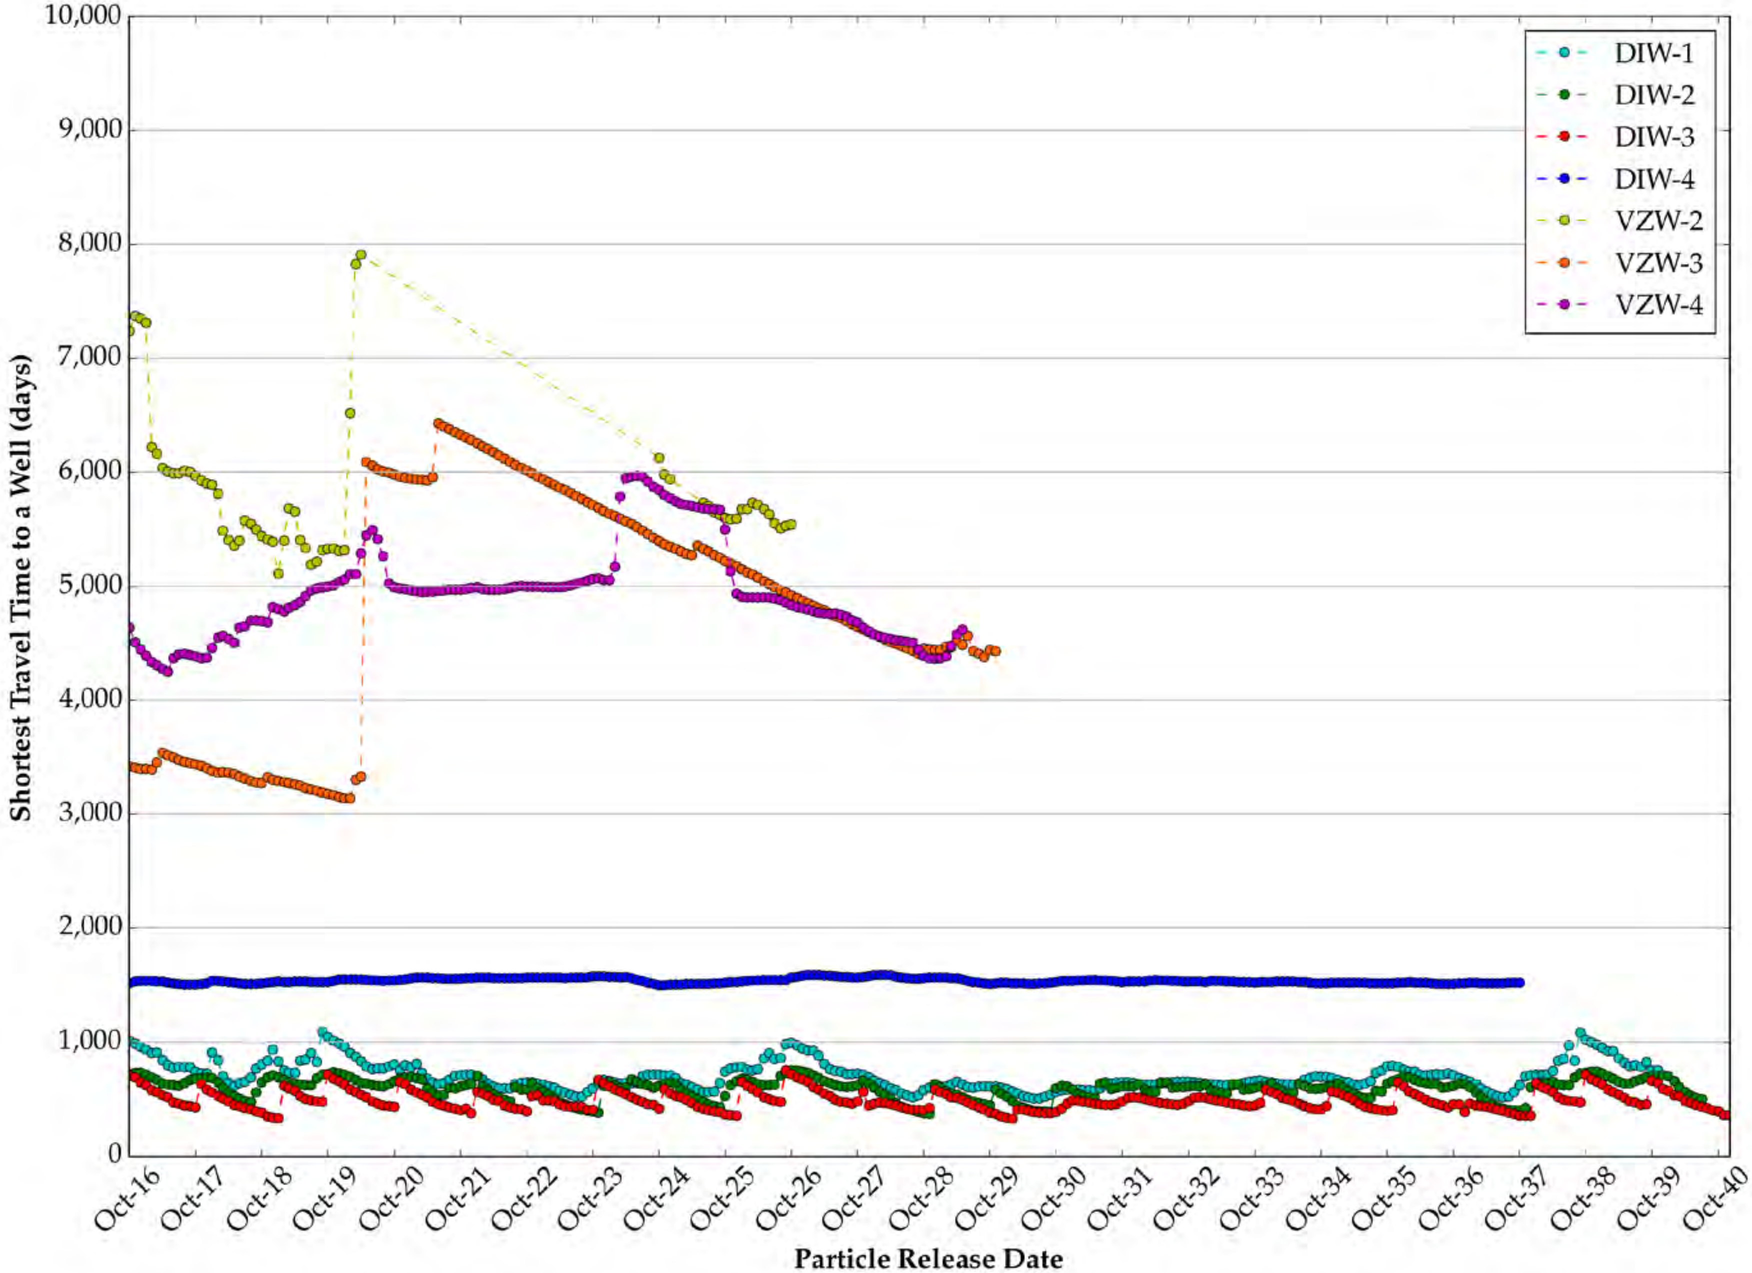

*Figure 18: Fastest Travel Times to a Pumping Well*

The vadose zone wells also display variations in minimum travel times throughout the simulation. These particles are initially released at shallow depths, above the influence of the large-capacity injection and extraction wells. The dynamics of the shallow layers in the model are mostly influenced by fluctuations in natural recharge and by the vadose zone injection itself. Variations in these factors can lead to saturation or desaturation of shallow model cells which in turn cause rapid changes in vertical and horizontal gradients in these cells. This type of behavior is likely to explain the stepped changes in minimum travel times that are seen in vadose zone wells VZW-2, VZW-3, and VZW-4.

The only production wells that capture particles released from the eight injection locations are the two ASR Well Sites, the Ord Grove #2 well; the Paralta well; and the Luzern well. The following tables summarize how particles from each injection site are captured by nearby wells under the Project scenario.

Table 2 shows the fastest travel times between each injection location and the six groups of extraction wells. A value is not shown if there was no particle travelling between the two wells.

*Table 2: Fastest Travel Times between Injection and Extraction Wells, in days*

| Extraction Well | Well of Origin | | | | | | | |
|---|---|---|---|---|---|---|---|---|
| | DIW-1 | DIW-2 | DIW-3 | DIW-4 | VZW-1 | VZW-2 | VZW-3 | VZW-4 |
| ASR 1&2 | - | 371 | 327 | 1,780 | - | - | - | - |
| ASR 3&4 | 724 | - | - | 3,074 | - | - | - | - |
| Luzern | - | - | - | - | - | - | 3,140 | - |
| Ord Grove | 3,718 | 1,952 | 1,052 | 1,497 | - | - | - | 4,250 |
| Paralta | 506 | 521 | 852 | 2,076 | - | 5,114 | - | - |

Note: — = no particle traveling between wells

Table 3 shows the percent of particles injected at each of the injection locations that were captured by each extraction well. This table only shows the fate of the captured particles – not the fate of all particles. As a result, the columns add to 100% for each scenario, even though most of the particles released from the vadose zone wells were not captured by the end of the simulation. The Paralta and Ord Grove 2 well capture the greatest share of the particles even though it takes considerably longer for particles to travel to these two wells, as shown on Table 2.

*Table 3: Percent of Particles Travel between Injection and Extraction Wells*

| Extraction Well | Well of Origin | | | | | | | |
|---|---|---|---|---|---|---|---|---|
| | DIW-1 | DIW-2 | DIW-3 | DIW-4 | VZW-1 | VZW-2 | VZW-3 | VZW-4 |
| ASR 1&2 | - | 16% | 44% | 3% | - | - | - | - |
| ASR 3&4 | 34% | - | - | 3% | - | - | - | - |
| Luzern | - | - | - | - | - | - | 100% | - |
| Ord Grove | 3% | 2% | 44% | 55% | - | - | - | 100% |
| Paralta | 63% | 82% | 12% | 39% | - | 100% | - | - |

Note: — = no particle traveling between wells

Figure 19 and Figure 20 show the path each particle takes from its initial injection location to either an extraction well or its final location when the simulation ends. Separate maps for paths originating from deep injection wells and paths originating from vadose zone wells are included. The particle tracks shown on each figure display the fate of particles that were released in the model period corresponding to February, 2030. This date was selected as it is the release period with the fastest travel times.

The particle path figures show that the northwestern-directed groundwater flow field dominates the migration of particles from the vadose zone wells while the local dynamics of the many deep injection and extraction wells dominate the migration of the particles from the deep injection wells. As noted above, there are several particle paths that fluctuate towards and away from the ASR wells before the particles are captured. These fluctuations are the result of the injection and extraction pattern at the ASR wells.

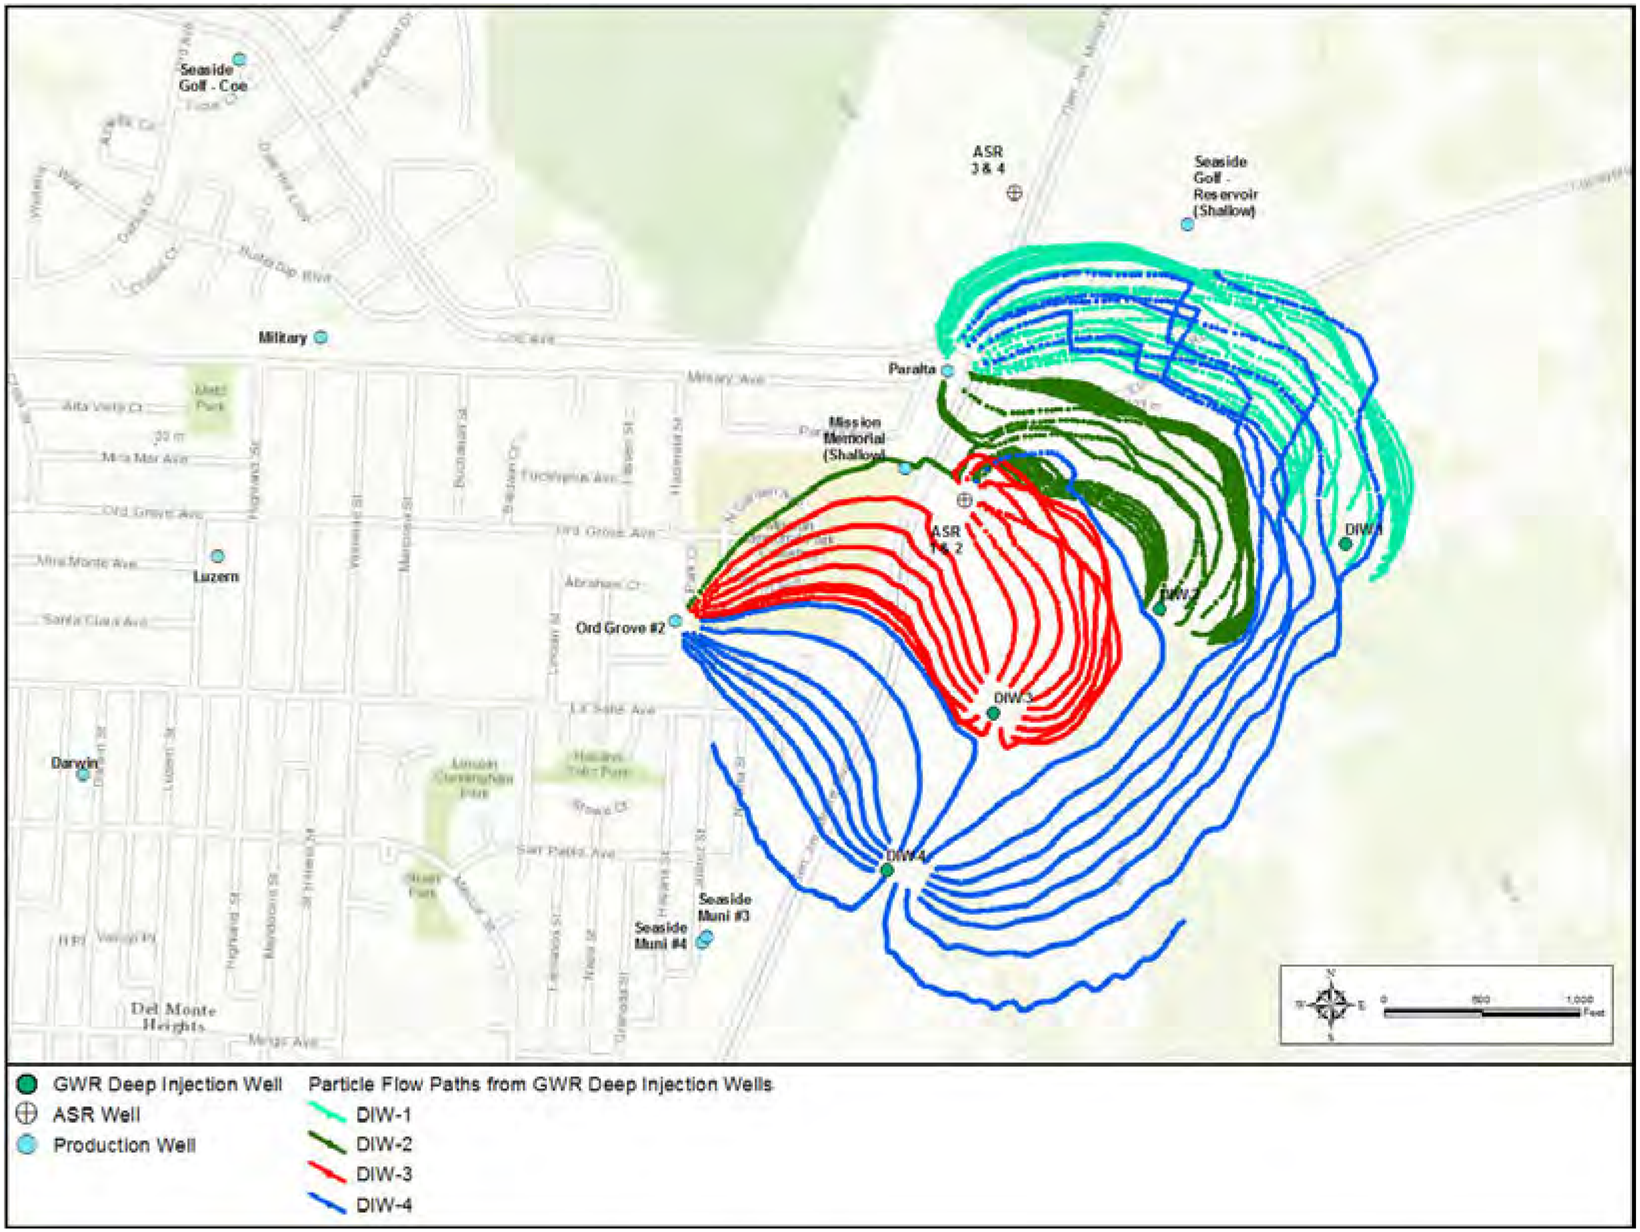

*Figure 19: Particle Paths from a Single Release in Deep Injection*

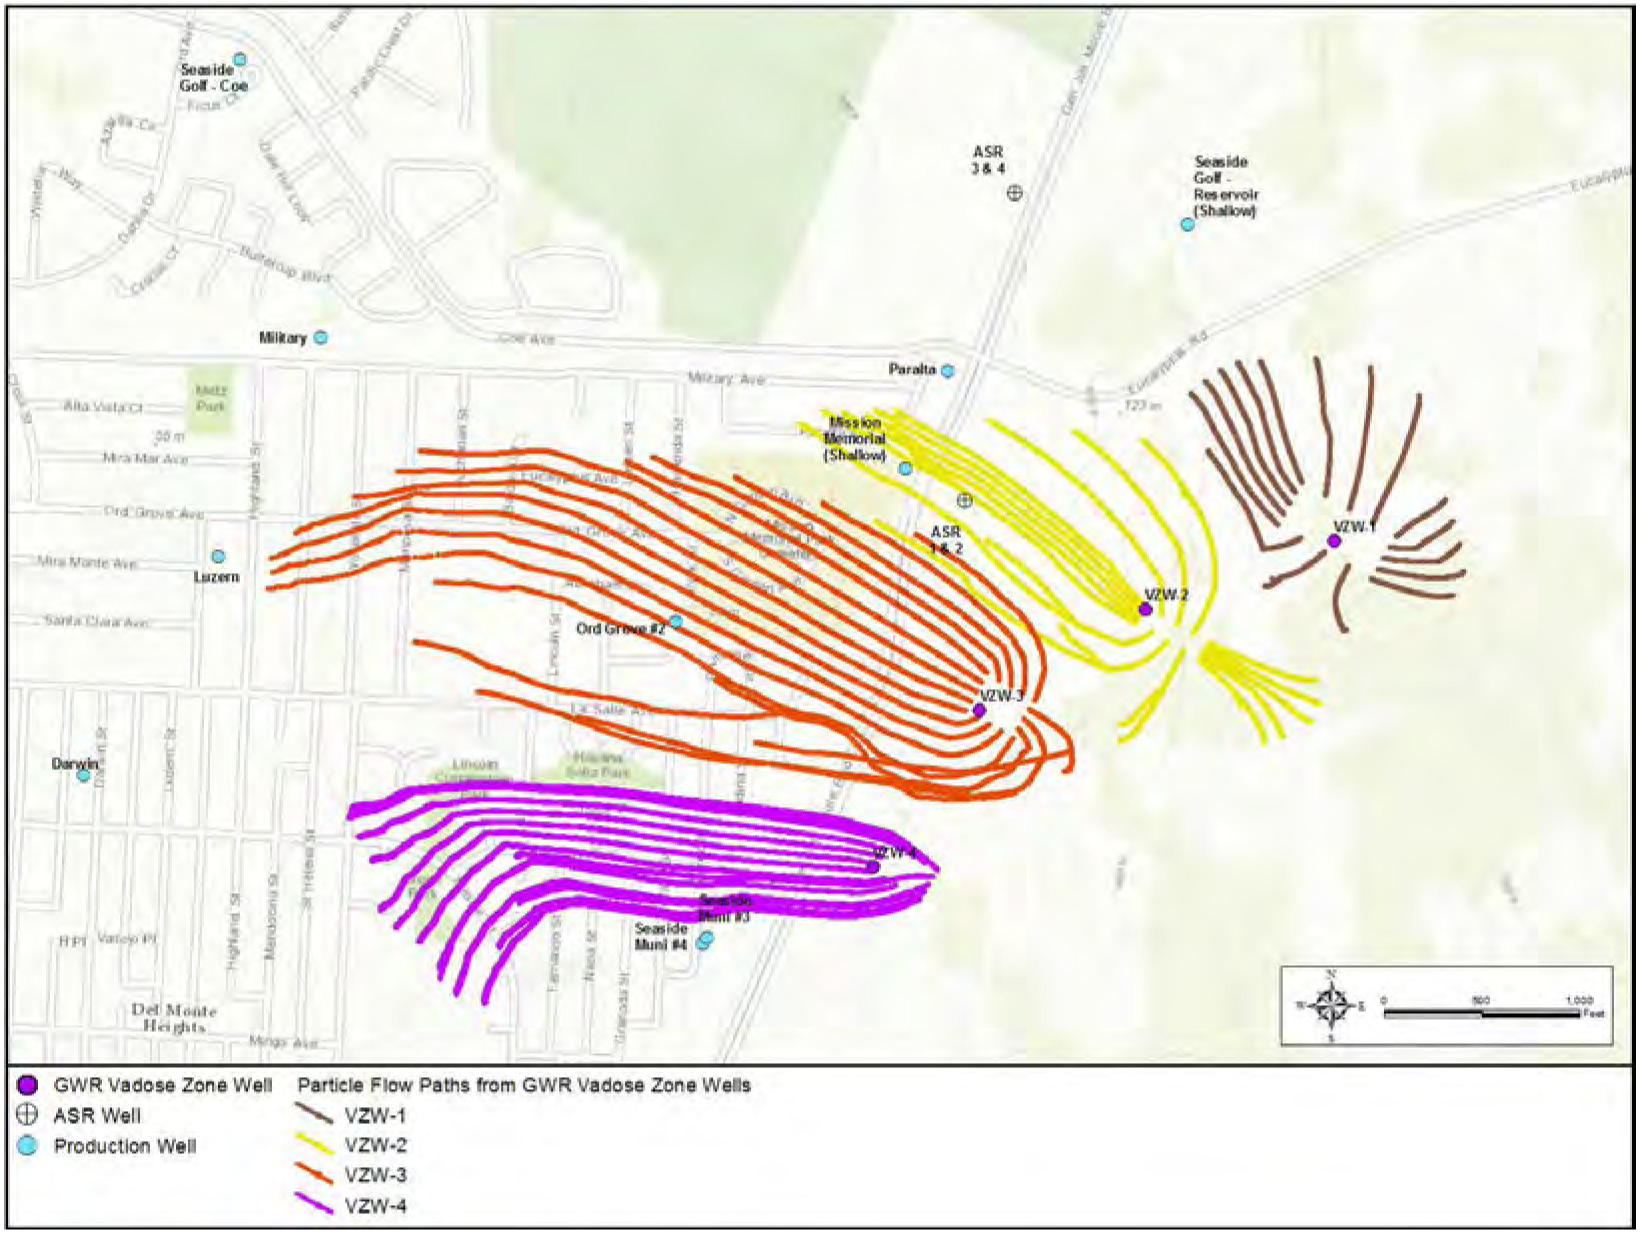

*Figure 20: Particle Paths from a Single Release in Vadose Zone*

Figure 21 and Figure 22 show the greatest particle extent from each injection location at four separate times. Separate maps for paths originating from deep injection wells and paths originating from vadose zone wells are included. Four times are shown: 90 days (yellow), 180 days (orange), 270 days (red), and 360 days (blue). These contours show the same general spatial pattern as Figure 19 and Figure 20 but represent the extent of all particles at any time rather than individual paths. The fourth (blue) contour, representing 360 days, is 33 days shorter than was taken by the fastest particle to travel from injection well DIW-3 to the ASR 1&2 Well Site.

# APPENDIX D

## Todd Groundwater

## Groundwater Quality Analytical Program – Laboratory Summary
## Tables D-1 and D-1A through D-1P

## Table D-1: Groundwater Quality Analytical Program - Laboratory Summary

| Laboratory | Analytes | Tables |
|---|---|---|
| Alpha Analytical Laboratory | Anions | D-1A |
| Alpha Analytical Laboratory/McCampbell Analytical | Metals (Including Major Cations) and Cr(VI) | D-1B |
| Alpha Analytical Laboratory | Conventional Chemistry and Other Parameters | D-1C |
| Alpha Analytical Laboratory | Chlorinated Pesticides and PCBs | D-1D |
| Alpha Analytical Laboratory | Nitrogen and Phosphorus Pesticides | D-1E |
| Alpha Analytical Laboratory | Organic Analytes | D-1F |
| Alpha Analytical Laboratory | Chlorinated Acids | D-1G |
| Alpha Analytical Laboratory | Carbamates | D-1H |
| Alpha Analytical Laboratory | Other Organic Compounds | D-1I |
| Alpha Analytical Laboratory | Volatile Organic Compounds (VOCs) | D-1J |
| Alpha Analytical Laboratory UL Laboratory and Pace Analytical | Semivolatile Organic Compounds (VOCs)+Dioxin | D-1K |
| Alpha Analytical Laboratory | Haloacetic Acids | D-1L |
| ALS Environmental | Nitroaromatics and Nitramines (Explosives) | D-1M |
| Weck Laboratories, Inc. | Pharmaceuticals and Personal Care Products (PPCPs) | D-1N |
| UL Laboratory and GEL Laboratories | Radiogenic: Gross Alpha, Beta; Radium 226 and 228, Strontium 90 | D-1O |
| ZyMax Forensics | Stable Isotopes of oxygen and hydrogen in water, nitrogen and oxygen in nitrate | D-1P |
| Asbestos TEM Laboratories, Inc. | Asbestos | D-1C |
| Isotech | Tritium (enriched) | D-1O |

**Notes:**
For abbreviation explanations see notes at end of Table D-1P.

Table D-1A: Anions

Oakland, CA 94612

# TECHNICAL MEMORANDUM

To: Bob Holden/MRWPCA

From: Stephen Hundt and
Derrik Williams

Date: December 16, 2015

Subject: GWR Project EIR: Cumulative Projects Modeling Results

## Executive Summary

The Monterey Regional Water Pollution Control Agency (MRWPCA) is developing the Pure Water Monterey Groundwater Replenishment Project (GWR Project). This project will recharge the Seaside groundwater basin with high-quality purified recycled water. This water will be subsequently extracted from the Seaside Basin for urban potable use. The GWR Project is being developed in partnership with the Monterey Peninsula Water Management District with a goal of supplying water to users within California-American Water Company's (Cal-Am) Monterey Service area. Cal-Am is simultaneously developing a seawater desalination project that will provide water supplies to the Seaside Basin and Monterey Peninsula as part of its Monterey Peninsula Water Supply Project (MPWSP). These two projects can be operated independently, or jointly; however, if the GWR Project is implemented, the desalination plant proposed by Cal-Am would be reduced in size from 9.6-mgd to 6.4 mgd. The cumulative analysis in the GWR Project's Environmental Impact Report (EIR) assesses the environmental impacts of operating the smaller desalination plant and the GWR Project jointly. The GWR Project EIR refers to the joint operation of the two projects as the Cumulative Projects. The MPWSP EIR refers to the joint operation of the two projects as the Variant Project. Because this analysis considers and incorporates the impacts of past, present, and reasonably foreseeable future projects that involve the Seaside Groundwater Basin, this analysis can also be used as the basis for analysis of future cumulative conditions with and without implementation of the two projects analyses in the two EIRs.

The calibrated groundwater model of the Seaside Groundwater Basin (HydroMetrics WRI, 2009) was used to estimate impacts from the Cumulative Projects. A predictive

model incorporating reasonable future hydrologic conditions was developed for this impact analysis. The groundwater model was calibrated through 2008; therefore the predictive model begins in 2009. The predictive model simulates a 33 year period: from 2009 through 2041.

Simulated future Carmel River flows were based on historical flow records. The amount of Carmel River water available for winter injection into the Seaside Basin was estimated by Monterey Peninsula Water Management District (MPWMD) staff. They compared historical daily streamflows with minimum streamflow requirements for each day, and then identified how much water could be extracted from the Carmel River for injection each month.

Cal-Am provided average monthly projections of both the groundwater injection and groundwater pumping needed to meet their anticipated future demands for their Variant Project. These projections were incorporated into the predictive model to the degree possible. Some modifications to Cal-Am's projections were needed to compensate for anticipated pumping capacity shortfalls in specific future years.

One additional modification to Cal-Am's projected groundwater pumping schedule was necessary to ensure adequate water was available during a potential five-year drought. Cal-Am may need to suspend its planned groundwater repayment plan during three years of the five-year drought. This is a reasonable assumption, because all water purveyors are expected to fully use any available water supplies during a drought.

Model results show that the Cumulative Projects Scenario is generally neutral or beneficial compared to the No Project conditions. Groundwater elevations are generally higher under the Cumulative Projects conditions than under the No Project conditions. These higher groundwater levels will tend to slow or stop seawater intrusion.

Particle tracking was used to estimate the travel time of GWR water from the point of recharge to the closest point of extraction. Particle tracking showed that the shortest travel time for any recharged GWR water is 334 days. Travel times of less than 12 months occur for 10 years of the 25-year simulation period when the GWR Project is in operation.

# Project Description

The Monterey Regional Water Pollution Control Agency (MRWPCA) is developing a Groundwater Replenishment (GWR) project. This project will recharge the Seaside groundwater basin with high-quality purified recycled water. The GWR Project is being developed in partnership with the Monterey Peninsula Water Management District with a goal of supplying water to users within California-American Water Company's (Cal-Am) Monterey Service area. Cal-Am is simultaneously developing a seawater desalination project that will provide water supplies to the Seaside Basin in Monterey Peninsula as part of its Monterey Peninsula Water Supply Project (MPWSP). The locations of the two projects' facilities, along with other operating production wells, are shown on Figure 1.

These two projects can be operated independently, or jointly; however, if the GWR Project is implemented, the desalination plant proposed by Cal-Am would be reduced in size from 9.6-mgd to 6.4 mgd. The cumulative analysis in the GWR Project's Environmental Impact Report (EIR) assesses the environmental impacts of operating the smaller desalination plant and the GWR Project jointly. The GWR Project EIR refers to the joint operation of the two projects as the Cumulative Projects. The MPWSP EIR refers to the joint operation of the two projects as the Variant Project. Because this analysis considers and incorporates the impacts of past, present, and reasonably foreseeable future projects that involve the Seaside Groundwater Basin, this analysis can also be used as the basis for analysis of future cumulative conditions with and without implementation of the two projects analyses in the two EIRs.

HydroMetrics Water Resources Inc. (WRI) has completed groundwater flow and particle tracking simulations of the proposed joint operation of the GWR and desalination plant projects. These simulations were undertaken to predict impacts on groundwater levels and the fate and travel time of injected GWR water under the joint operation of these two projects. This modeling was completed in support of the GWR project's environmental impact report (EIR). The GWR Project's EIR is being developed in concurrence with the EIR for Cal-Am's desalination project. The simulations described below predict the impacts of the combined implementation of both the 6.4-mgd desalination plant and the proposed GWR Project. This modeling effort is generally consistent with the required cumulative analysis for both EIRs, based on a review of all past, present, and reasonably foreseeable future projects that may change the groundwater conditions in the Seaside Basin during the modeling period. For the remainder of this memorandum this joint project will be referred to as the Cumulative Projects.

*Figure 1: Production and GWR Injection Well Locations*

# Model Background and Assumptions

The calibrated groundwater model of the Seaside Groundwater Basin (HydroMetrics WRI, 2009) was used to estimate the impacts from the Cumulative Projects. A predictive model incorporating reasonable future hydrologic conditions was developed for this impact analysis. The groundwater model was calibrated through 2008; therefore the predictive model begins in 2009. The predictive model simulates a 33 year period: from 2009 through 2041.

## PREDICTED HYDROLOGY ASSUMPTIONS

The hydrology (rainfall and recharge) used to calibrate the groundwater model was applied to the predictive model. To extend the hydrology through the predictive period, the 1987 through 2008 hydrology data were used to simulate model years 2009 through 2030, and the 1987 through 1997 hydrology data were then repeated for 2031 through 2041 (Figure 2). This is the approach that has been adopted for all predictive models of the Seaside Basin since 2009. By using this hydrology, even during the period January 2009 to present when actual hydrology is known, the model runs can be used to compare relative groundwater levels, but not to assess absolute Basin conditions.

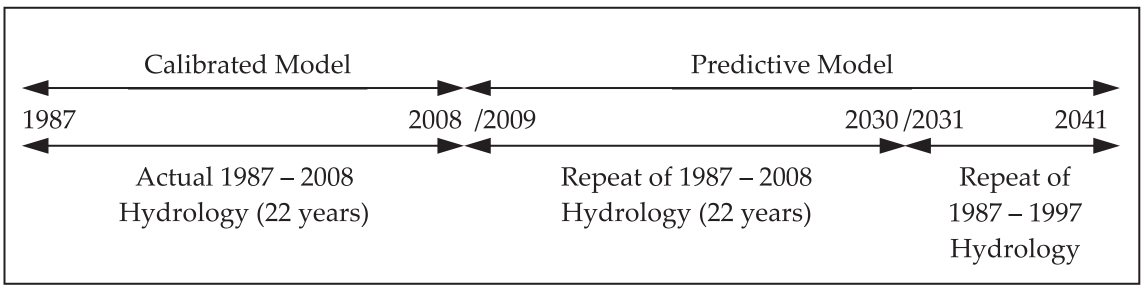

*Figure 2: Repetition of Hydrology for Predictive Model*

## PREDICTED CARMEL RIVER FLOW AND INJECTION ASSUMPTIONS

Monterey Peninsula Water Management District (MPWMD) estimated the amount of Carmel River water available for ASR injection for the predictive simulation based on historical streamflow records. Because the future simulated hydrology is based on the historical hydrology between 1987 and 2008, the future streamflows are expected to be the same as the historical streamflows. MPWMD staff compared historical daily streamflows between water year 1987 and water year 2008 with minimum streamflow requirements for each day. This allowed MPWMD to identify how many days in each month ASR water could be extracted from the Carmel River. Using a daily diversion rate of 20 acre-feet per day, MPWMD calculated how many acre-feet water from the Carmel River could be injected into the ASR system each month. Figure 3 shows the estimated available monthly ASR injection volumes for the predictive simulation. Appendix A includes the historic and projected ASR Wells Site injection schedule that was developed by MPWMD. The Carmel River water available for injection shown on Figure 3 was divided between the ASR 1&2 Well Site and the ASR 3&4 Well Site.

## PREDICTED GWR RECHARGE ASSUMPTIONS

The simulated GWR Project recharges varying volumes of water each year, with an average of 3500 acre-feet recharged per year. The amount of water recharged each year depends upon whether the predicted hydrology is in a drought or non-drought year, and upon a reasonable assumption of the rules for banking and delivering drought reserve water to the Castroville Seawater Intrusion Project (CSIP). In non-drought years, GWR Project deliveries to the Seaside Basin are 3700 acre-feet. This provides 3500 acre-feet for extraction by Cal-Am, and provides 200 acre feet groundwater storage for a Drought Reserve. The Drought Reserve is capped at 1000 acre feet. When the Drought Reserve is full and drought conditions do not exist, the GWR Project delivers 3500 acre feet to the Seaside Basin for extraction by Cal-Am. In drought years when Drought Reserve water is available, the GWR Project delivers less than 3500 acre-feet to the Seaside Basin, and Cal-Am draws from the Drought Reserve.

GWR Project water is recharged through four deep wells and four vadose zone wells in the predictive model. Of the GWR water delivered to the Seaside Basin, 90% of the water is injected into the Santa Margarita aquifer through four deep injection wells, and the remaining 10% is recharged into the Paso Robles aquifer through four vadose zone wells.

Figure 4 shows the volume of water recharged by the GWR Project for each water year in this modeling analysis. While the annual recharge of GWR water varies from year to year, the recovery of water through Cal-Am's pumping wells is maintained at a constant 3500 acre-feet every year in accordance with the GWR Project objectives. The monthly recharge schedule used for the model that includes an accounting and description of the CSIP Drought Reserve program is shown on the 11 x 17 sized table at the end of this technical memorandum.

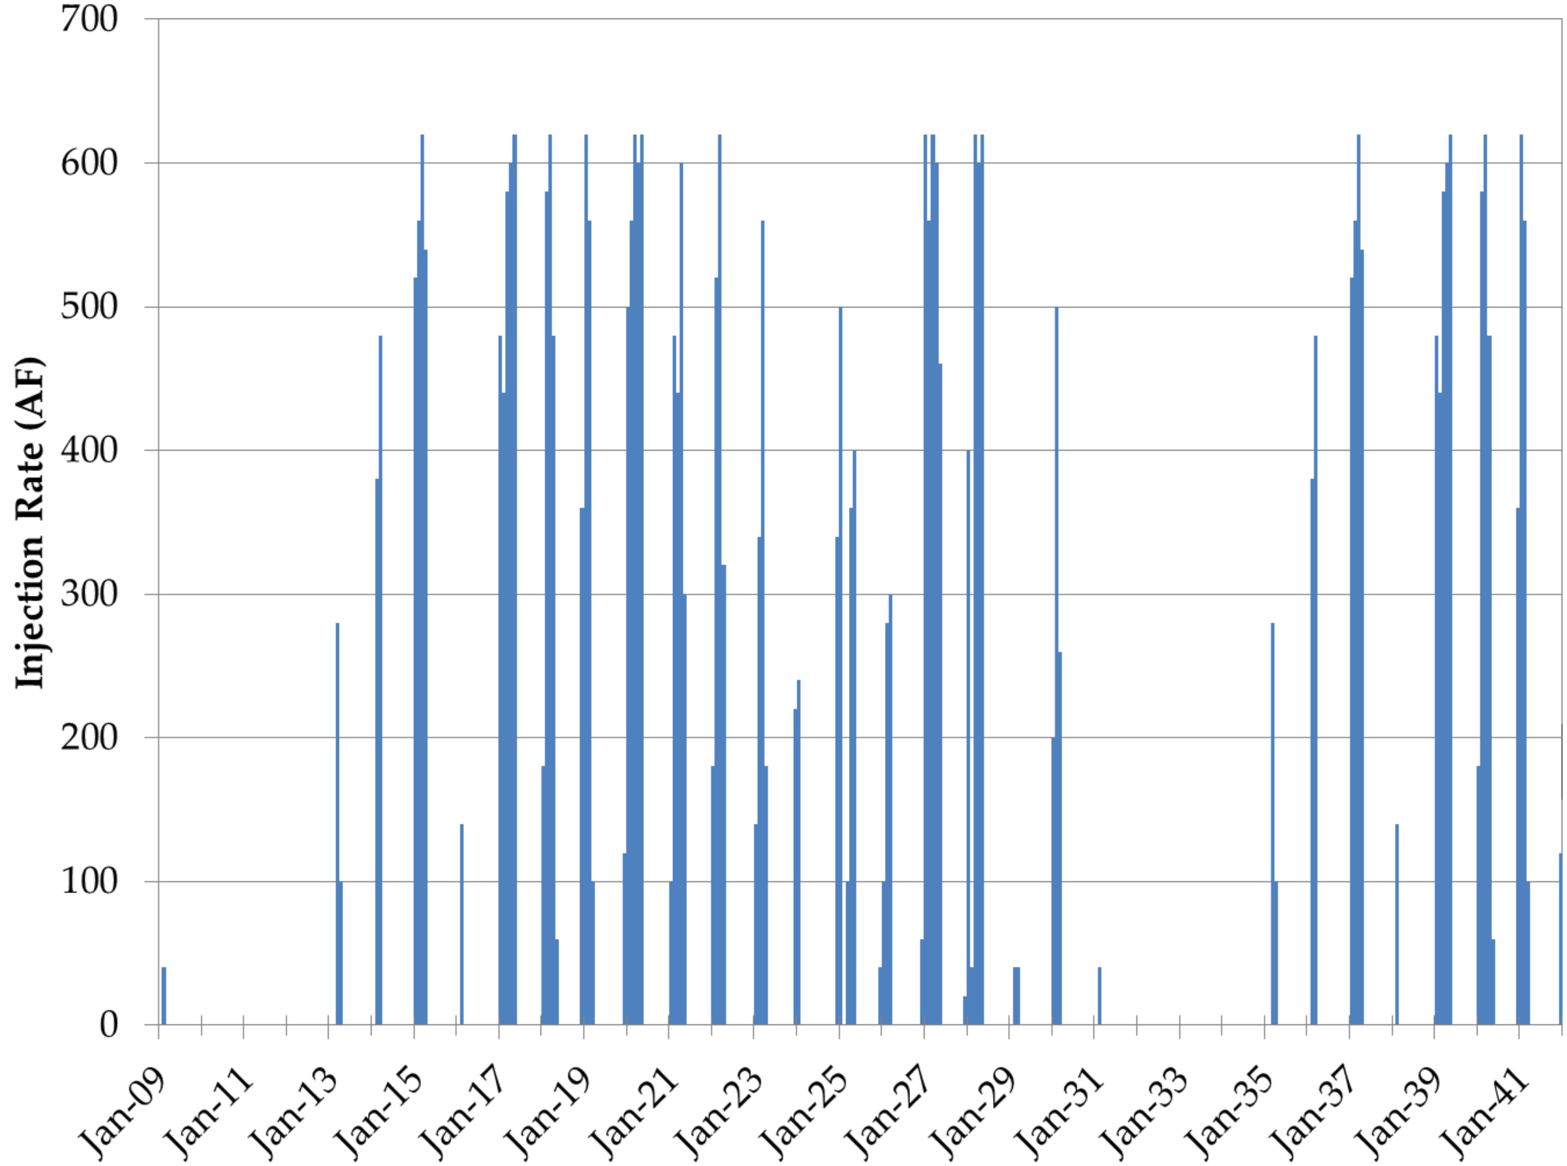

*Figure 3: Estimated Monthly Carmel River ASR Injection Volumes*

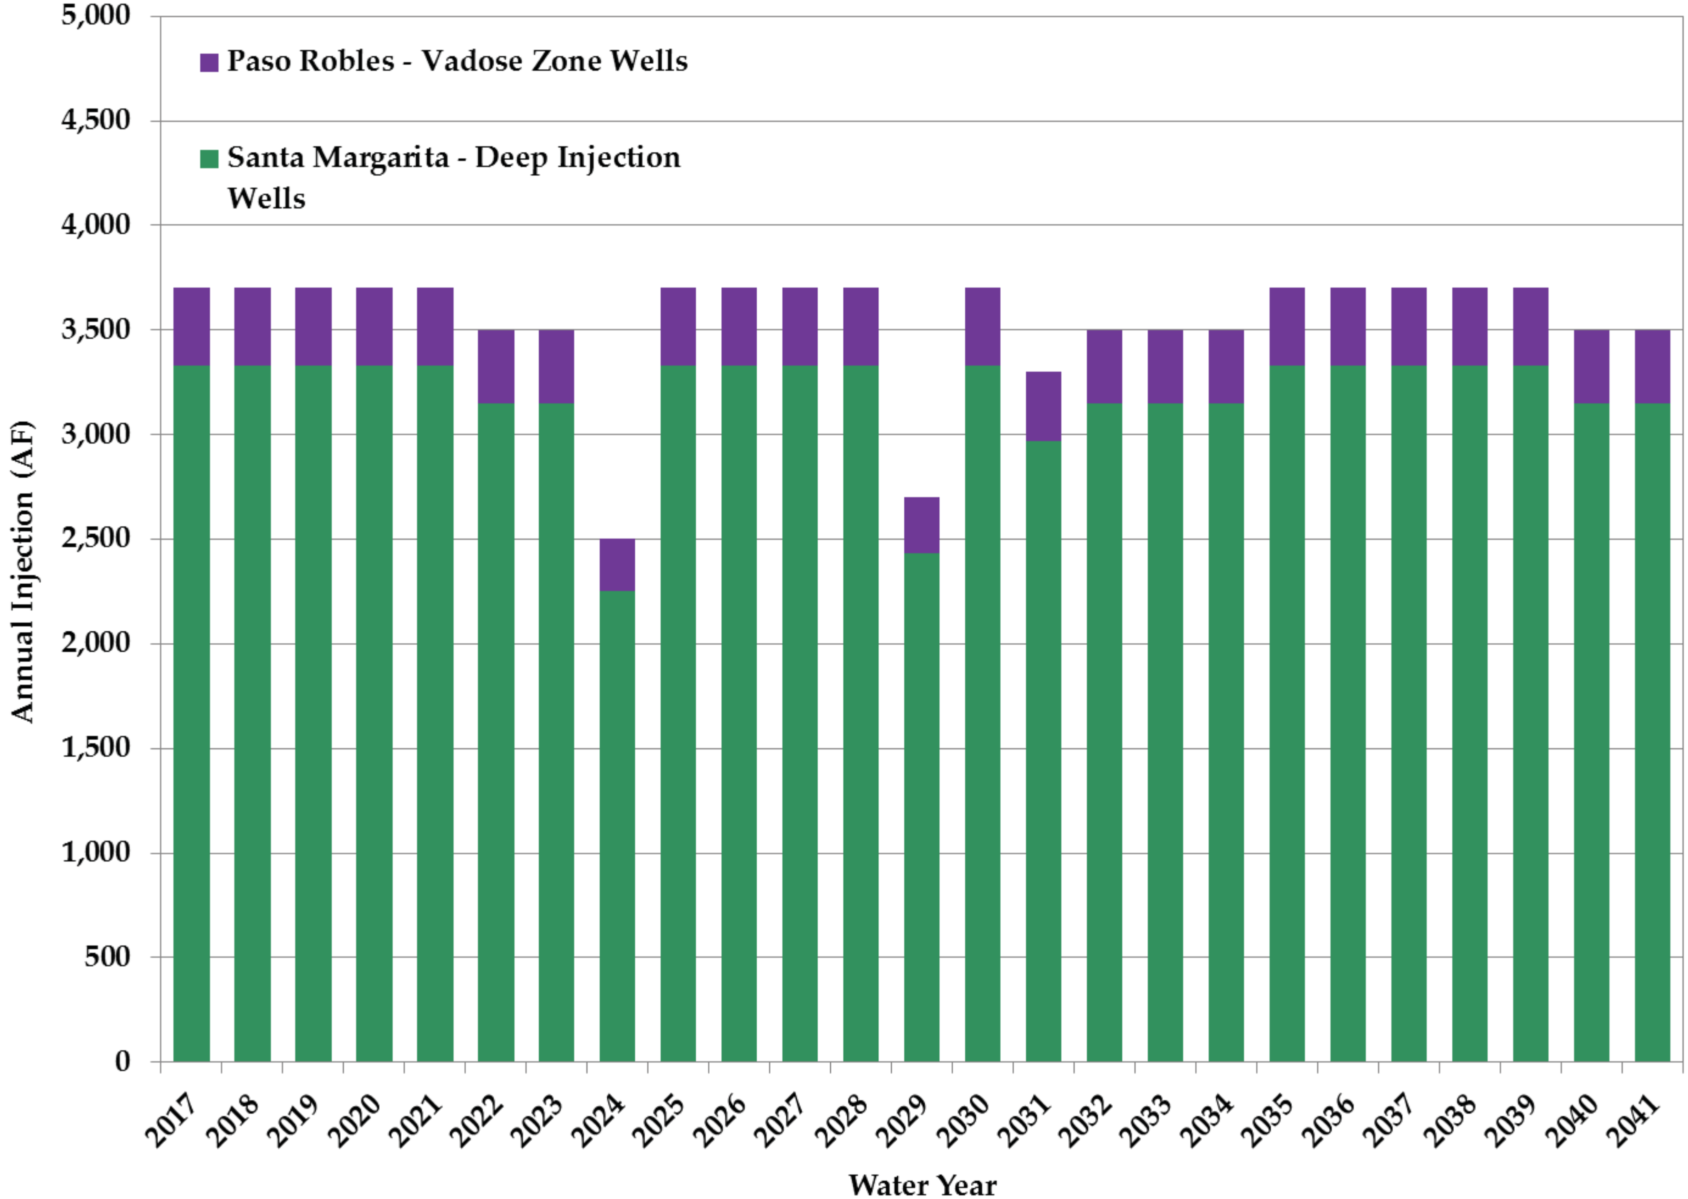

*Figure 4: Annual GWR Recharge*

## PREDICTED MPWSP DESALINATED WATER INJECTION ASSUMPTIONS

The MPSWP small desalination plant that is part of the MPSWP Variant Project will provide 590 acre-feet per year of desalinated water for injection through the ASR wells. This desalinated water injection will occur on a regular schedule between October and April of each year. For the predictive simulation, this desalinated water is injected entirely at the ASR 5&6 Well Site between October and February. Injection of desalinated water in March and April is allocated to either the ASR 1&2 Well Site or to the ASR 3&4 Well Site, depending on well availability. Moving the desalinated water injection away from the ASR 5&6 well site allows any disinfection byproducts in the groundwater around these wells to dissipate, as required by permit, prior to using them for extraction. ASR 5&6 wells are therefore available for pumping in May. Figure 5 shows the predicted injection rates of Carmel River and desalinated water for the three pairs of ASR wells over the simulation period.

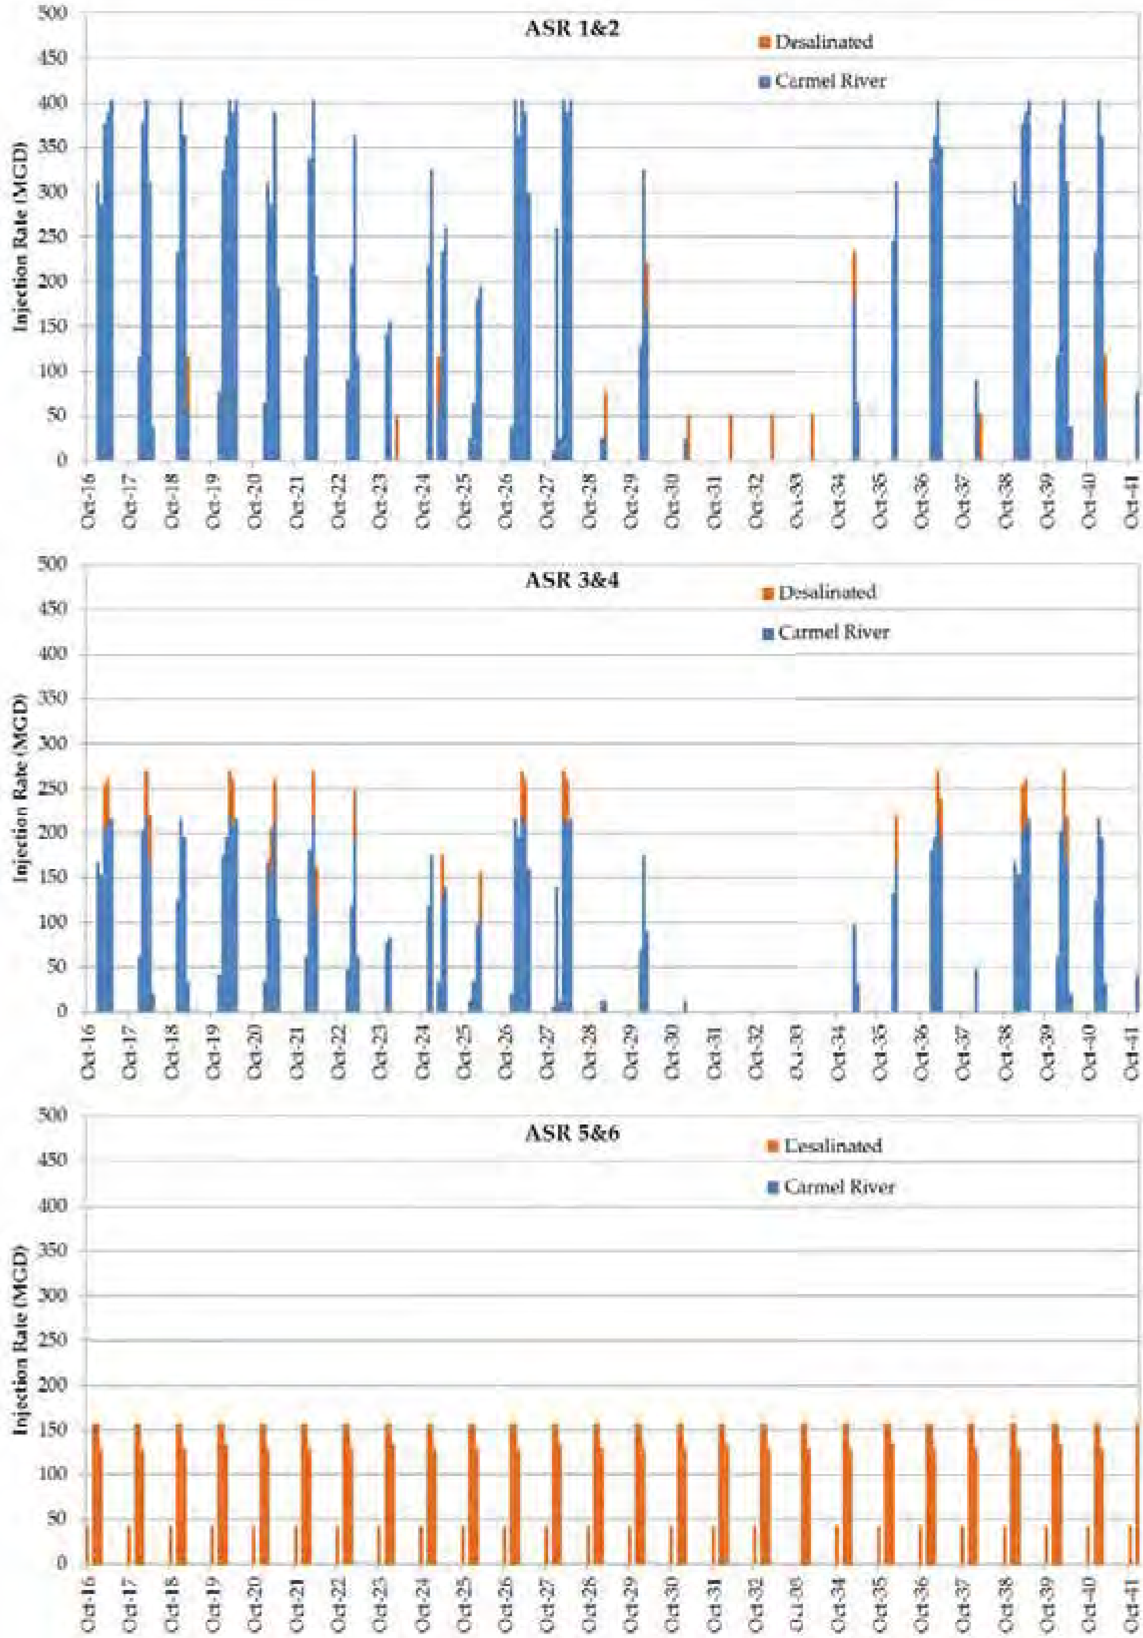

*Figure 5: Monthly ASR Injection of Carmel River and Desalinated Water*

## Predicted Cal-Am Monthly Supply and Demand Assumptions

Table 1 shows the average monthly supply and demand estimates provided by Cal-Am for the Cumulative Projects. This table was produced by Cal-Am as a part of their effort to analyze the groundwater impacts of the MPWSP Variant Project, and MPWMD and MRWPCA agreed to use it as the basis for the Cumulative Projects pumping and injection projections. Cal-Am's monthly supply and demand in the Cumulative Projects simulations was held as consistent as possible with Table 1. However, because the values on Table 1 represent average monthly supply and demand, adjustments were required to accommodate known constraints on well operations and water supply variability in the Seaside Basin.

Future Cal-Am pumping will come from five existing Cal–Am wells, two existing ASR sites, and one planned ASR site. These wells and ASR sites include:

- Luzern #2 Well
- Ord Grove #2 Well
- Paralta Well
- Playa #3 Well
- Plumas #4 Well
- ASR Wells 1&2 Site
- ASR Wells 3&4 Site
- ASR Wells 5&6 Site

Data supplied by Cal-Am show that the pumping capacity of their five existing wells is 5.26 million gallons per day (MGD), or approximately 16 acre-feet per day. Based on conversations with MPWMD, we assumed that each ASR well site could either produce 4.32 million gallons per day or inject 4.32 million gallons per day. The total pumping capacity of the five existing wells and three ASR well sites is therefore 18.22 million gallons per day, or approximately 55.8 acre-feet per day.

This total pumping capacity is reduced when one or more ASR sites are unavailable for extraction. One reason an ASR site may be unavailable for extraction is that it may be used for injection, and an ASR site cannot simultaneously inject and extract water. Furthermore, MPWMD's previous experience has shown that ASR wells are required to rest for up to 60 days after injection to reduce the occurrence of disinfection byproducts and meet permit requirements. As a result, we conservatively estimated that an ASR well site is unavailable for extraction during any month that it has injected water, and for two additional months following injection. Information from MPWMD helped determine when ASR wells are unavailable for extraction. MPWMD developed a likely future ASR Well Site injection and extraction schedule based on the hydrology incorporated into the predictive simulation. Appendix A includes the historic and projected ASR Wells Site injection schedule that was developed by MPWMD. The MPWMD injection and extraction schedule identifies months when ASR wells are not available to pump groundwater, either because they are being used for injection or they are resting. For simulated months when the ASR wells were not available for extraction, Cal-Am's pumping capacity was reduced by 4.32 MGD for each unavailable site. The possible pumping capacities are shown in Table 2.

*Table 2: Total Extraction Capacity*

| Number of ASR Sites Available for Extraction | Total Capacity (MGD) | Total Capacity (GPM) | Total Capacity (AF/day) |
|---|---|---|---|
| 3 | 18.2 | 12,653 | 55.8 |
| 2 | 13.9 | 9,653 | 42.6 |
| 1 | 9.6 | 6,653 | 29.4 |
| 0 | 5.3 | 3,653 | 16.1 |

For some years in MPWMD's predicted future pumping schedule, ASR wells must inject Carmel River Water in the spring months, leaving them unavailable for extraction in early summer while they rest. This can result in inadequate extraction capacity to meet the pumping demand specified in Table 1. Due to this capacity constraint, HydroMetrics WRI has identified and accommodated three types of years in setting up the predictive model:

1. Years in which there are no constraints, and the average extraction numbers from Table 1 are used in the model (i.e., no modification)

2. Years in which Carmel River water injection continues into April, and the extraction capacity from existing wells is inadequate to meet Cal-Am's expected demands in June. We refer to this as Modification 1.
3. Years in which Carmel River water injection continues into May and the extraction capacity from existing wells is inadequate to meet Cal-Am's expected demands in June and July. We refer to this as Modification 2.

The pumping constraints identified above are resolved by increasing the amount of water that is assumed to be delivered directly from the Carmel River to the distribution system during June and/or July. The delivery of Carmel River water to the distribution system is then reduced in December to ensure that the annual total use of Carmel River water remains at Cal-Am's right of 3,376 acre-feet per year. This approach to resolving the pumping constraints has the advantages of being easily implemented, not requiring any new wells, and meeting Cal-Am's and MPWMD's water rights and permit restrictions on the Carmel River. Carmel River extractions under the proposed changes would still comply with the impending SWRCB Cease and Desist Order.

Table 3 shows the modifications made to the average monthly supply sources for years when capacity is constrained in June. ~~**Error! Reference source not found.**~~ Table 4 shows the modifications made to the average monthly supply sources for years when pumping capacity is constrained in both June and July. The cells highlighted in red show the changes from Cal-Am's original supply schedule.

## PREDICTED PUMPING ASSUMPTIONS

HydroMetrics WRI made a number of assumptions for the predictive simulation about future pumping rates by various entities in the Seaside Basin. These assumptions were consistent with assumptions developed for previous modeling exercises in the basin. Pumping assumptions were developed for standard producers, alternative producers, golf courses, and Cal-Am.

### WATER YEAR 2009 THROUGH WATER YEAR 2012 PUMPING

Actual pumping and injection data for all wells from January 2009 through December 2012 are included in the predictive simulation.

### MUNICIPAL PUPMPING FROM WATER YEAR 2013 ONWARDS

Predicted pumping by the City of Seaside and the City of Sand City follows the triennial reductions prescribed in the Amended Decision (California American Water v. City of Seaside et al., 2007). These pumping reductions are designed to reduce basin-wide pumping to the approximate safe yield of 3,000 acre-feet per year by 2021.

### CAL-AM PUMPING FROM WATER 2013 ONWARDS

A number of assumptions were necessary to estimate Cal-Am's monthly pumping rates and pumping distribution.

#### Well Priority Assumptions

HydroMetrics WRI assumed that Cal-Am's monthly pumping from the Seaside Basin is allocated among their available wells with the following order of preference:

1. ASR 5&6
2. ASR 3&4
3. ASR 1&2
4. Ord Grove #2
5. Paralta
6. Luzern
7. Playa #3
8. Plumas #4

The pumping during any month was first allocated to the ASR wells up to their capacity. Pumping was then allocated to the Ord Grove #2 well up to its capacity, and so on.  As discussed above, ASR wells are unavailable for extraction if they are injecting water, or have injected water at any time during the previous 3 months.  Cal-Am agreed that these are reasonable assumptions during coordination meetings in 2014. Using this well priority sequence, Figure 6 shows Cal-Am's monthly pumping by well in the predictive simulation.  Figure 7 shows the monthly distribution of ASR water injection and extraction by well in the predictive simulation.

**Water Available for Cal-Am During Droughts**

The predictive simulation includes a five-year drought between 2030 and 2034.  During this drought, virtually no Carmel River water is injected into the Seaside Basin (Figure 5).  Therefore, Cal-Am will need to draw from ASR water previously stored in the basin during this drought.  Figure 8 shows an analysis of the amount of ASR water stored in the Seaside Basin for the entire simulated period.  This figure shows that, without pumping modifications, Cal-Am will deplete all the water previously stored in the Seaside Basin after the five-year drought, and will run a storage deficit.

To avoid a storage deficit, HydroMetrics WRI assumed that Cal-Am would suspend its groundwater repayment plan during the five-year drought.  This is a reasonable assumption: during a drought, we expect all water purveyors will fully use any available water supplies.  Analysis by HydroMetrics WRI showed that Cal-Am would need to suspend its groundwater repayment plan for only three years of the five year drought to avoid depleting all the water previously stored in the Seaside Basin.  Figure 9 shows that Cal-Am would always retain some amount of stored water in the Seaside Basin by suspending its groundwater repayment plan for only three years.  This suspension of repayment would be in accordance with, and would not undermine, the long-term goal of maintaining the groundwater basin as a water supply source. HydroMetrics WRI assumed that Cal-Am would restart its groundwater repayment schedule after the drought ends, and would continue this plan until the full amount of repayment is achieved.

Using these assumptions, Figure 10 shows were Cal-Am's water comes from during both drought and non-drought years.  The green area on this figure represents the current year's GWR Project water that is extracted by Cal-Am.  The purple area represents the MPWSP desalinated water that was injected during the current year, and subsequently extracted by Cal-Am.  The red area represents native groundwater pumped by Cal-Am.  The blue area represents Carmel River water that was injected during the current year, and subsequently extracted by Cal-Am.  The orange area represents ASR water stored by Cal-Am in previous years.

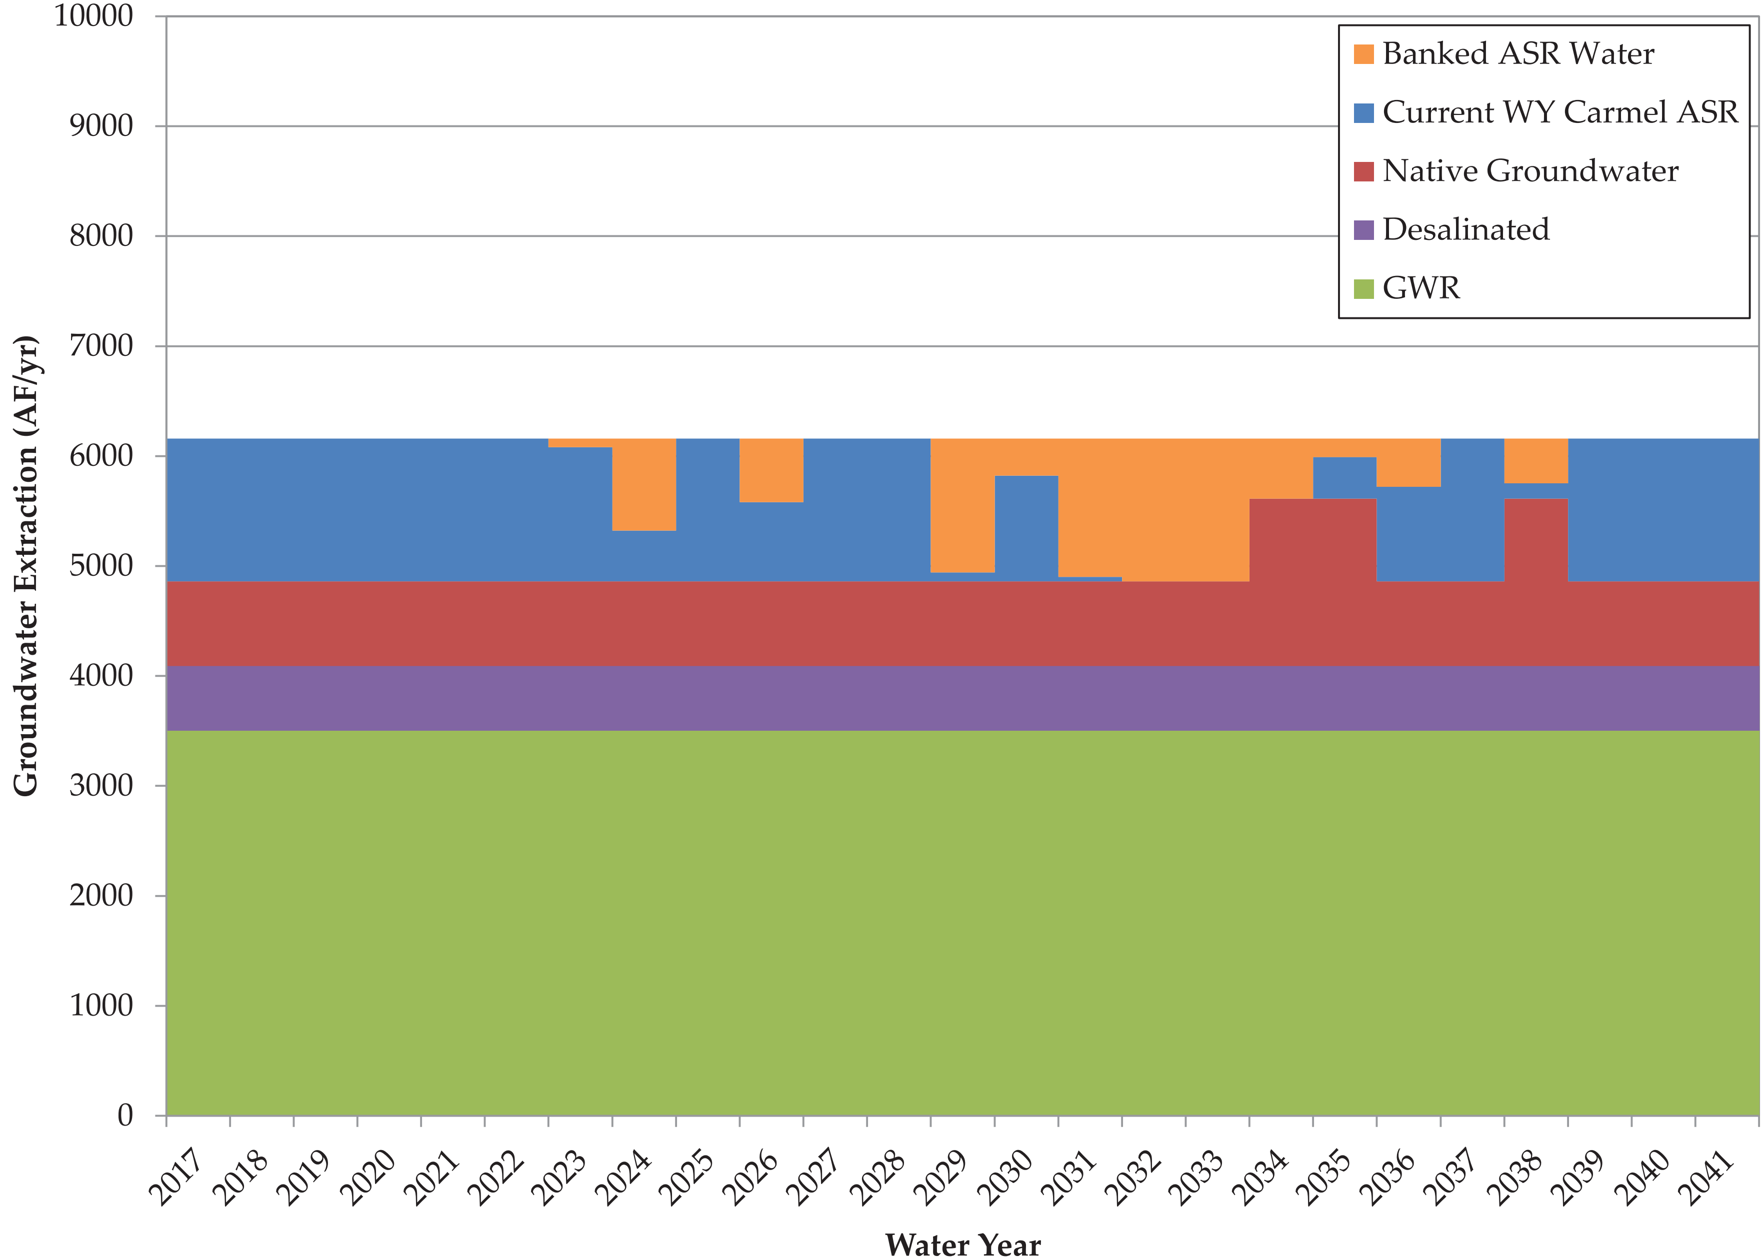

*Figure 10: Annual Cal-Am Water Allocation by Water Right Source*

## GOLF COURSE PUMPING FROM WATER YEAR 2013 ONWARDS

Predicted golf course pumping is based on the hydrologic year. For example, pumping in January 2015 equals the amount pumped in January 1993, because the simulated 2015 hydrology is based on 1993 hydrology. This ensures that the demand corresponds to the hydrology. If the amount pumped by a Producer pre-adjudication exceeds the Producer's adjudicated right, pumping was capped at the Producer's adjudicated amount.

Additional golf course pumping adjustments accounted for in the simulation are:

- The Bayonet and Blackhorse golf courses pump no water until September, 2016. This is based on an in-lieu replenishment program in which Marina Coast Water District provides water in-lieu of the City of Seaside pumping from the Seaside Basin. The City of Seaside expects to start pumping its golf course wells again starting September 2016.

- In 2007, Bayonet and Black Horse golf courses had irrigation upgrades that have reduced irrigation demand by approximately 10% from historical amounts.

- The City of Seaside expects to begin pumping an average of 360 AFY from its wells for golf course supply starting in September 2016. These projected quantities were used rather than basing demand on the hydrology year.

## PREDICTED ALTERNATIVE PRODUCER AND PRIVATE PUMPING

Predicted alternative producer pumping is set at measured Water Year (WY) 2011 volumes from WY 2013 onwards. All other pumpers that are not covered by the Decision, including Cal Water Service and private wells, also pump at WY 2011 volumes from WY 2013 onwards.

Pumping exceptions in the simulation are:

- Water for SNG, which is an Alternative Producer, is supplied from Cal-Am wells under an agreement with Cal-Am. When the SNG site is developed they will be supplied with water by Cal-Am, who will use SNG's water right of 149.7 acre-feet/year. Based on input from the property owner, Ed Ghandour, project construction planned to start in 2013, and use 25 AFY of water; however, construction is now estimated to occur in 2015 or later. Water usage thereafter is estimated to be:

- 2014 - 30 AFY
- 2015 – 50 AFY
- 2016 onwards – 70 AFY

Because the SNG project has been delayed, it is unclear what SNG's future water use might be. Therefore, HydroMetrics WRI adopted the water use estimates listed above to be consistent with previous modeling efforts.

## Particle Tracking Approach

Particle tracking was conducted to estimate the fate and transport of GWR water under the Cumulative Projects. Particles were first introduced around all eight GWR Project injection wells on the simulated period corresponding to October 1, 2016. A new set of particles was released into the model at the beginning of every month until the end of the simulation in 2042. Each month, 40 particles were released from each injection well. Every particle was tracked through the model until it terminated at an extraction well, or until the end of the simulation period in 2042. By introducing the particles continuously, we ensured that there were particles introduced and tracked during times when the travel times would be the fastest.

Particles were placed along the edges of each of the model cells that contained the injection and vadose wells. This strategy is necessary to ensure that the particles are carried outward in all directions in the same manner that water would travel radially from a well. Placing many particles at the exact location of the well results in only a single path taken by all particles. While the approach of placing particles around the edge of the model cell gives a more accurate picture of the dispersal pattern of the water from the injection wells, it also places particles closer to the extraction wells, effectively resulting in faster simulated travel times than actual travel times.

Particles are captured by wells not when they reach the exact location of the extraction wells, but when they reach the edge of the cell that contains an extraction well. This also leads to faster simulated travel times. The results shown below should therefore be considered conservative estimates because actual travel times will be greater than simulated.

# Model Results

## Groundwater Elevation Results

The impact of the Cumulative Projects on groundwater elevations was determined by comparing results from the Cumulative Projects simulation with results from the GWR Project and No-Project scenarios. The No-Project scenario simulates future groundwater conditions without either the GWR or MSPWP projects. The Project scenario simulates future groundwater conditions with the GWR Project but without the MPWSP Project. The assumptions of each of these scenarios are documented in the *Groundwater Replenishment Project Description Development Modeling* (HydroMetrics WRI, October 2, 2013), where they are referred to as the No-Project and Project-High scenarios.

Simulated groundwater elevations from the three scenarios were compared at the following seven wells:

- ASR 1&2 Well Site
- City of Seaside #3
- Ord Grove #2
- Paralta
- Luzern
- PCA-West (Shallow)
- PCA-West (Deep)

Figure 11 shows the location of these seven wells and the GWR injection wells. These seven wells span the area between the GWR injection wells and the coast. Several of the major extraction wells for the GWR Project water are included in this set of wells.

Hydrographs for simulated groundwater elevations under the Cumulative Projects, Project, and No-Project scenarios are shown on Figure 12 through Figure 18. The blue lines represent the simulated static groundwater elevation under the No-Project scenario; the green lines represent the simulated static groundwater elevation under the GWR Project scenario, and the purple lines represent the simulated static groundwater elevation under the Cumulative Projects scenario. The simulated groundwater elevations are generally higher under the Cumulative Projects scenario than under the No-Project and GWR Project scenarios. This is primarily the result of reduced extraction of native groundwater that occurs under the Cumulative Projects scenario. Cal-Am has proposed foregoing extracting 700 acre-feet/year of groundwater from 2017 through 2041 as repayment for past overpumping. The reduced use of native groundwater under the Cumulative Projects scenario translates to a relative increase in storage and rising groundwater elevations. Figure 9 shows the annual use of native groundwater under each scenario. Note that Figure 9 spans the entire simulation period from 2009-2041, while Figure 10 spans the simulation period 2017-2041.

Simulated groundwater elevations around Cal-Am production wells, such as Ord Grove #2, are also higher under the Cumulative Projects scenario because they have lower extraction rates than under the GWR Project and No-Project scenarios. As discussed in the Predicted Pumping Assumptions section above, the Cumulative Project scenario assumes that Cal-Am will use the ASR Well Sites to meet a greater portion of their pumping needs than under the Project and No-Project scenario. This is accompanied by reducing pumping from other Cal-Am well in the coastal subarea, including Ord Grove #2. Figure 20 compares the extraction rates of the Ord Grove #2 well under the No-project, Project, and Cumulative Project scenarios.

The increased use of ASR wells under the Cumulative Projects scenario also leads to increased groundwater elevations in the shallower model layers, where the Ord Grove #2 and Paralta wells draw a portion of their extracted water but the ASR wells do not. This behavior is seen in hydrographs of the Luzern and PCA-West Shallow wells (Figure 16 and Figure 17). Under the GWR Project scenario, drops in groundwater elevations in the Luzern and PCA-West Shallow wells were observed almost immediately with the beginning of GWR Project operation in 2017. This drop was caused by increases in pumping that were not offset immediately by the injection of water that took place in a deeper layer. Under the Cumulative Projects scenario, however, there is an overall reduction in pumping from the shallower layers.

Groundwater elevations in the Cumulative Projects scenario are below those of the GWR Project and No-Project scenarios for some short time periods. This is observed only in wells that penetrate the deep aquifer, including the ASR 1&2 Well Site, the Paralta well, and the PCA-West Deep well. These reductions occur during the summer months of the simulated drought period between 2030 and 2034. For each of these years, winter groundwater levels under the Cumulative Projects scenario are high relative to the No-Project and GWR Project scenarios, drop to a relatively low levels during the summer months, and then quickly recover again to a relatively high level during the next winter. This behavior can be explained by the increased use of use of ASR wells under the Cumulative Projects scenario. Under the Cumulative Project scenario, more water is drawn from the deep aquifer layer, but the effect of the increased pumping is quickly offset by injection in the same layer. During the drought years, however, heavy pumping continues despite four consecutive years without any injection of Carmel River water to help offset the effect of pumping. Furthermore, with no injection of Carmel River water, the ASR wells are rested for fewer months and take an even greater share of the pumping than under a typical year.

Comparing GWR Project and No-Project Hydrographs of the PCA-West Deep and PCA-West Shallow wells allows us to evaluate how the Cumulative Project may impact seawater intrusion in the Seaside Basin. The simulated groundwater elevations at the PCA-West Deep and PCA-West Shallow wells are higher under the Cumulative Projects scenario than under the GWR Project and No-Project scenarios, indicating that the combined GWR and desalination project would not worsen the potential for seawater intrusion at this location. Instead, it appears that the Cumulative Projects would cause this location to become less vulnerable to seawater intrusion.

## Particle Tracking Results

Figure 21 shows how travel times between the GWR Project injection wells and the nearest extraction wells vary depending upon time of release. The horizontal axis represents the time at which groups of particles were released from the injection wells and the vertical axis represents time in days it took for the fastest particle to reach an extraction well. Each dot represents the time travelled by the fastest particle. The light blue, green, red, and dark blue dots show travel times from the locations of the deep injection wells DIW-1, DIW-2, DIW-3, and DIW-4, respectively. The black, yellow, orange, and magenta dots show travel times from the locations of the vadose zone wells VZW-1, VZW-2, VZW-3, and VZW-4, respectively.

The fastest particles are those released from well DIW-3, and captured at the ASR 1&2 Well Site. The fastest time any particle takes to travel from an injection well to a nearby extraction well is approximately 334 days. Travel times from deep injection well DIW-1 are the next fastest; taking approximately 543 days for the fastest particles to reach the ASR 3&4 Well Site. The fastest particles released at the remaining wells take between 2 and 22 years to reach an extraction well, with particles released from vadose zone well VZW-1 never reaching an extraction well after 24 years of simulation.

For most of the wells, there is a notable variation throughout the simulation in the minimum travel time taken by the released particles. For all four deep injection wells, the variations in travel times are strongly influenced by the ASR wells. These ASR wells both inject and extract water throughout the simulation period, thereby impacting groundwater gradients. These ASR wells sometimes draw particles in and sometimes repel them, creating greatly different trajectories depending on when a particle approaches the ASR wells. For example, particles that are released from well DIW-3 in the early winter and captured by wells ASR 1&2 in the late fall experience the fastest travel times. These particles approach the ASR 1&2 wells during the summer pumping season and are captured before any injection begins in the winter. Particles that approach the ASR wells during simulated drought years, experience less seasonal variation in travel times and faster travel times. During these years, particles encounter little to no injection of Carmel River water that would repel them from their path, and at the same time feel a greater a pull from ASR wells that have an extended pumping season under dry conditions.

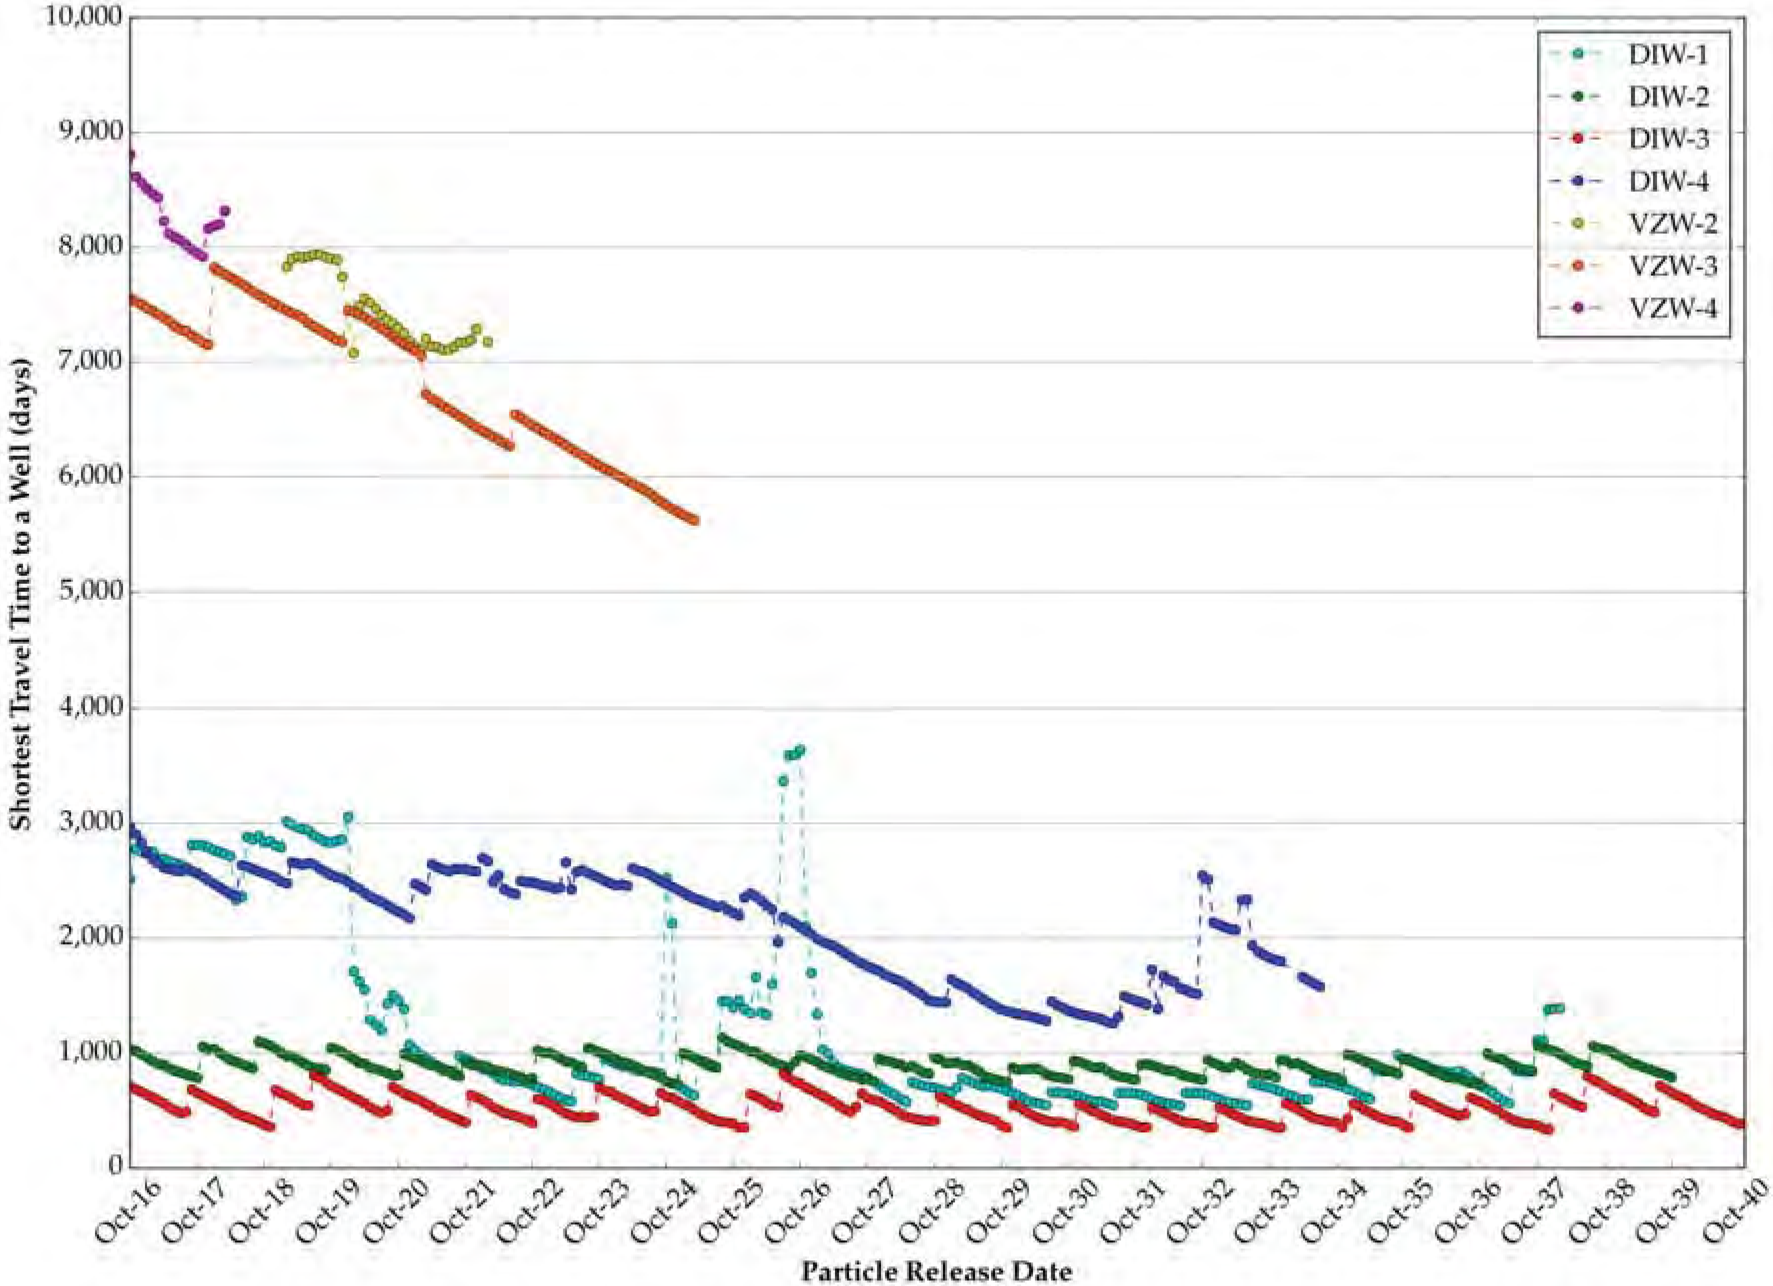

*Figure 21: Fastest Travel Times to a Pumping Well*

The vadose zone wells also display variations in minimum travel times throughout the simulation. These particles are initially released at shallow depths, above the influence of the large-capacity injection and extraction wells. The dynamics of the shallow layers in the model are mostly influenced by fluctuations in natural recharge and by the vadose zone injection itself. Variations in these factors can lead to saturation or desaturation of shallow model cells which in turn cause rapid changes in vertical and horizontal gradients in these cells. This type of behavior is likely to explain the stepped changes in minimum travel times that are seen in vadose zone wells VZW-2, VZW-3, and VZW-4.

The only production wells that capture particles released from the eight injection locations are the three ASR Well Sites, the Ord Grove #2 well; the Paralta well; and the Luzern well. Table 5 and Table 6 summarize how particles from each injection site are captured by nearby wells under the Cumulative Projects scenario.

Table 5 shows the fastest travel times between each injection location and the six groups of extraction wells. A value is not shown if there was no particle travelling between the two wells.

***Table 5: Fastest Travel Times between Injection and Extraction Wells, in Days***

| **Extraction Well** | **Well of Origin** | | | | | | | |
|---|---|---|---|---|---|---|---|---|
| | DIW-1 | DIW-2 | DIW-3 | DIW-4 | VZW-1 | VZW-2 | VZW-3 | VZW-4 |
| ASR 1&2 | - | 834 | 334 | 1,259 | - | - | - | - |
| ASR 3&4 | 543 | 720 | 1,217 | 2,070 | - | - | - | - |
| ASR 5&6 | 2,515 | 4,068 | 6,116 | 5,828 | - | - | - | - |
| Luzern | - | - | - | - | - | - | 5,626 | - |
| Ord Grove | - | - | 3,788 | 2,583 | - | - | - | 7,924 |
| Paralta | - | 870 | 1,040 | 2,125 | - | 7,081 | - | - |

Note: — = no particle traveling between wells

Table 6 shows the percent of particles injected at each of the injection locations that were captured by each extraction well. This table only shows the fate of the captured particles – not the fate of all particles. As a result, the columns add to 100% for each scenario, even though most of the particles released from the vadose zone wells were not captured by the end of the simulation. The Paralta, Luzern, and Ord Grove 2 wells capture the greatest share of the particles originating from the vadose zone wells; while the ASR 3&4 Well Site and ASR 5&6 Well Site capture the greatest share of particles originating from the deep injection wells.

*Table 6: Percent of Captured Particles that Travel between Injection and Extraction Wells*

| Extraction Well | Well of Origin | | | | | | | |
|---|---|---|---|---|---|---|---|---|
| | DIW-1 | DIW-2 | DIW-3 | DIW-4 | VZW-1 | VZW-2 | VZW-3 | VZW-4 |
| ASR 1&2 | - | 2 | 60% | 6% | - | - | - | - |
| ASR 3&4 | 63% | 89% | 32% | 49% | - | - | - | - |
| ASR 5&6 | 37% | 2% | 1% | 5% | - | - | - | - |
| Luzern | - | - | - | - | - | - | 100% | - |
| Ord Grove | - | - | 1% | 38% | - | - | - | 100% |
| Paralta | - | 7% | 6% | 2% | - | 100% | - | - |

Note: — = no particle traveling between wells

Figure 22 and Figure 23 show the path each particle takes from its initial injection location to either an extraction well or its final location when the simulation ends. Separate maps for paths originating from deep injection wells and paths originating from vadose zone wells are included. The particle tracks shown on each figure display the fate of particles that were released in the model period corresponding to December, 2037. This is the release date corresponding to the fastest travel times.

Figure 22 and Figure 23 show that the northwestern-directed groundwater flow field dominates the migration of particles from the vadose zone wells while the local dynamics of the many deep injection and extraction wells dominate the migration of the particles from the deep injection wells. As noted above, there are several particle paths that fluctuate towards and away from the ASR wells before the particles are captured. These fluctuations are the result of the injection and extraction pattern at the ASR wells. The deep particles released in December 2037 that are not captured by the nearby ASR 1&2, ASR 3&4, Ord Grove #2, or Paralta wells flow northward toward the ASR 5&6 wells, but are not captured before the end of the simulation (Figure 22).

*Figure 22: Particle Paths from a Single Release in Deep Injection*

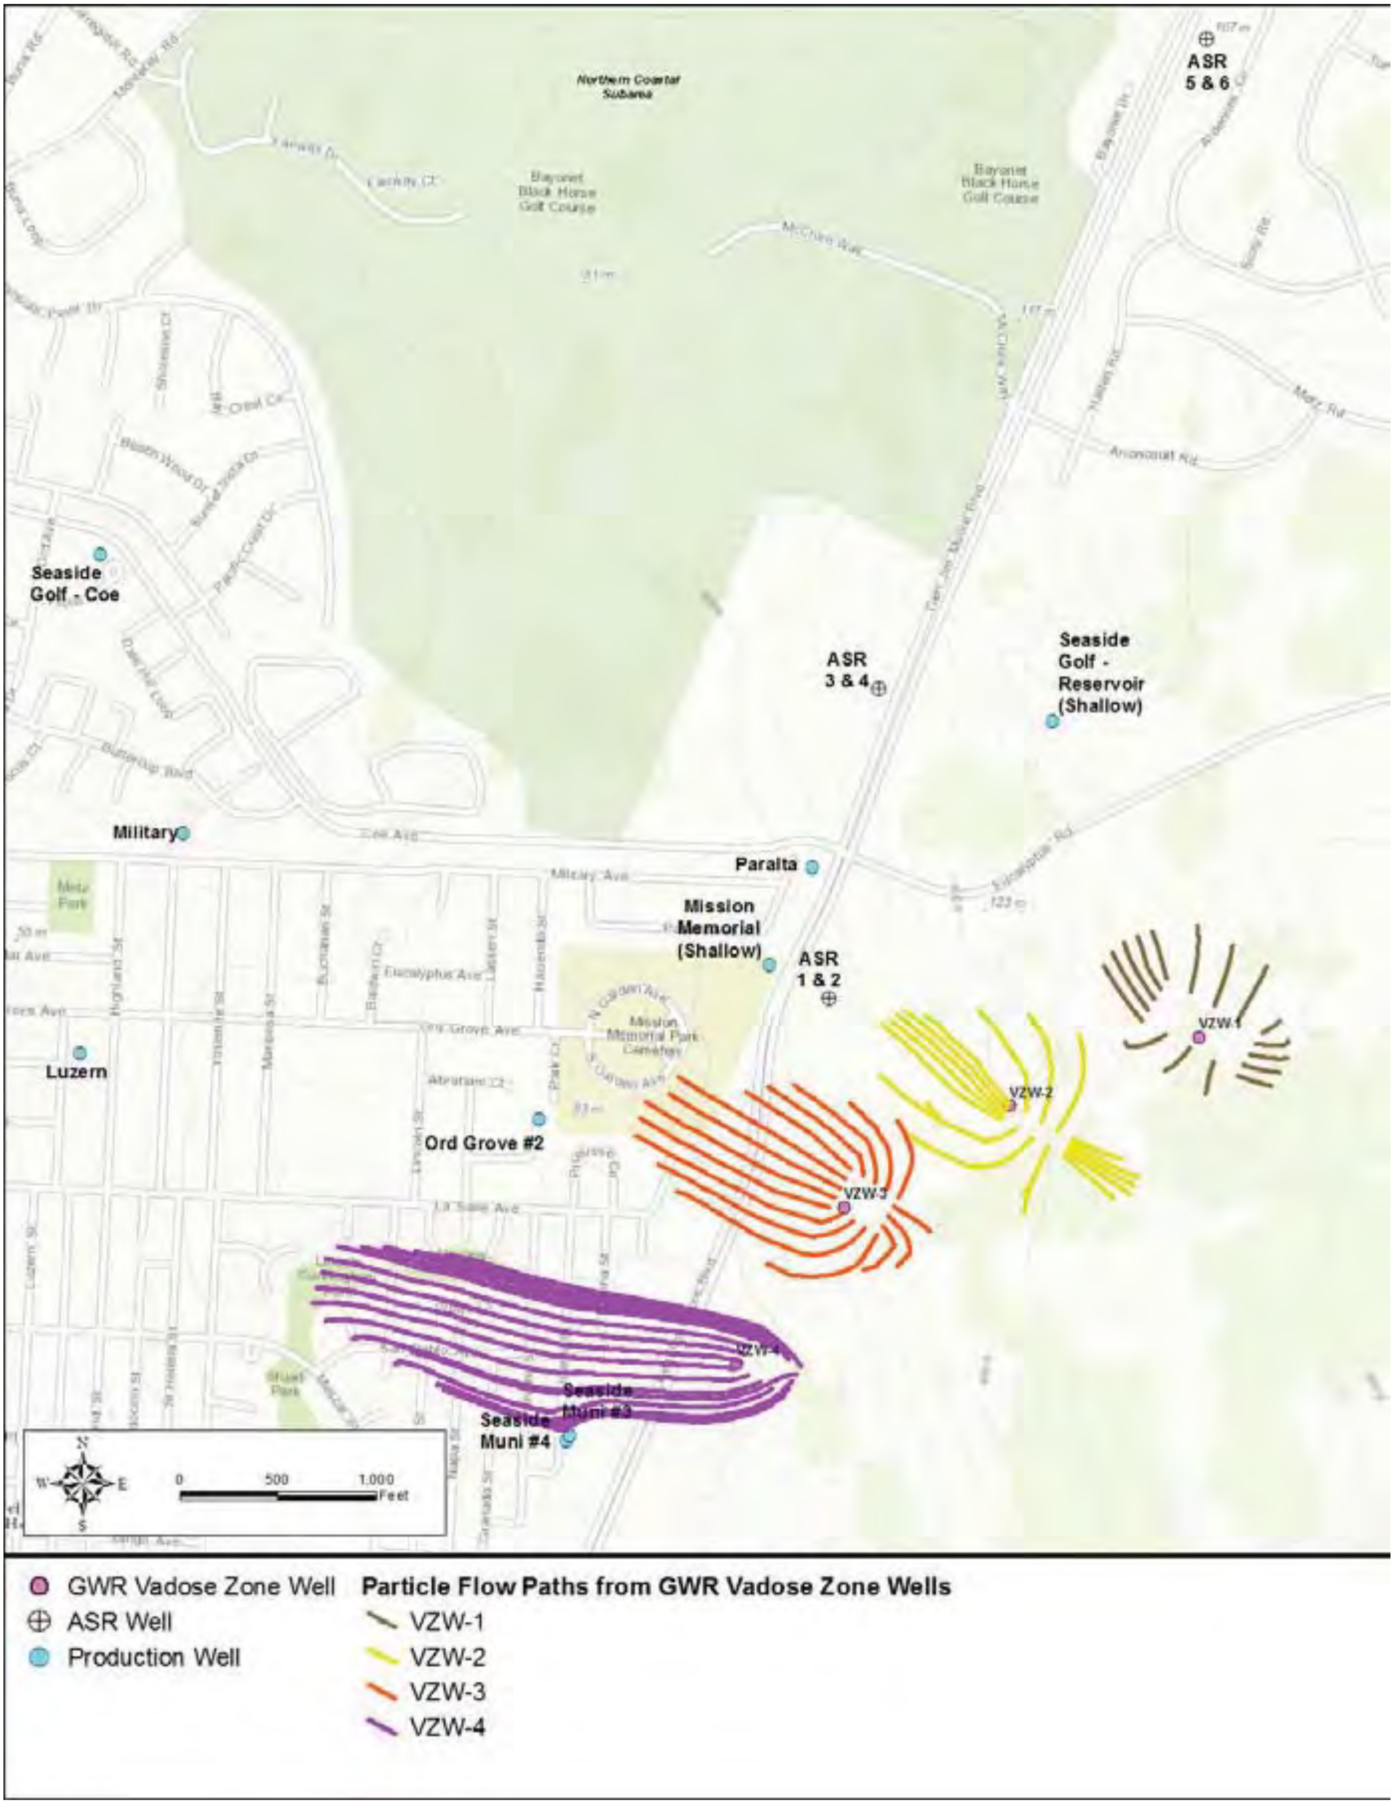

*Figure 23: Particle Paths from a Single Release in Vadose Zone*

Figure 24 and Figure 25 show the greatest particle extent from each injection location at four separate times. Separate maps for paths originating from deep injection wells and paths originating from vadose zone wells are included. Four times are shown: 90 days (yellow), 180 days (orange), 270 days (red), and 360 days (blue). These contours show the same general spatial pattern as Figure 22 and Figure 23 but represent the extent of all particles at any time rather than individual paths.

# Memorandum Regarding Pure Water Monterey Groundwater Replenishment Project - Impacts of Changes in Percolation at the Salinas Industrial Wastewater Treatment Facility on Groundwater and the Salinas River

*This page is intentionally blank.*

TODD GROUNDWATER

February 11, 2015

## TECHNICAL MEMORANDUM

**To:** Alison Imamura, Denise Duffy and Associates

**From:** Gus Yates, Senior Hydrologist, Todd Groundwater

**Re:** Pure Water Monterey Groundwater Replenishment Project: Impacts of Changes in Percolation at the Salinas Industrial Wastewater Treatment Facility on Groundwater and the Salinas River

## 1. INTRODUCTION

The Salinas Industrial Wastewater Treatment Facility (Salinas Treatment Facility) is located adjacent to the Salinas River about 3 miles southwest of the City of Salinas. The plant is owned and operated by the City of Salinas to treat and dispose of water primarily used to wash and prepare vegetable crops at industrial food processing facilities in Salinas. The Salinas Treatment Facility consists of an aeration pond for treatment of incoming water and three large percolation ponds that dispose of water by percolation and evaporation. Additional disposal capacity during the high-inflow season (May-October) is provided by drying beds and by temporary Rapid Infiltration Basins (RIBs) located between the main ponds and the Salinas River channel. **Figure 1** shows the locations of the ponds, RIBs, drying beds, Salinas River, shallow monitoring wells at the Salinas Treatment Facility and nearby irrigation wells.

Water that percolates from the ponds either flows a short distance through the subsurface and emerges as seepage into the Salinas River or flows downward to the shallow aquifer that is present in some places at depths of 0-80 feet, above the regionally extensive Salinas Valley Aquitard. The shallow aquifer is not used directly as a source of water supply, but gradual downward percolation from the shallow aquifer is a source of recharge to the 180-Foot aquifer, which is used for water supply in the Salinas region.

Wastewater currently treated at the Salinas Treatment Facility is one of several supplemental sources of water proposed for recycling and reuse for the Pure Water Monterey Groundwater Replenishment Project (GWR Project). Other sources include municipal wastewater, Blanco Drain, the Reclamation Ditch, Tembladero Slough and urban stormwater runoff from parts of Monterey and Salinas. A description and map of the source waters are included in section 2.7.1 of the GWR Project Draft Environmental Impact Report (DEIR). These sources would be diverted to the municipal wastewater system in varying amounts depending on availability, demand, and conditions of the various permits and agreements. The source waters would all be conveyed to the regional wastewater treatment plant (RTP) operated by Monterey Regional Water Pollution Control Agency (MRWPCA), located next to the Salinas River several miles downstream of the Salinas Treatment Facility. Some of the treated water would be delivered to agricultural users in the Castroville Seawater Intrusion Project (CSIP) service area, which encompasses 12,000 acres of coastal cropland north of the Salinas River (see map in Figure 2-2 of the GWR Project DEIR) . The rest of the water would be further purified at an advanced water treatment facility to be built within the RTP site and then conveyed south for injection into the Seaside Groundwater Basin. The injected water would augment the basin yield to replace existing sources of potable water that serve the Monterey Peninsula area.[1]

The GWR Project would alter the operation of the Salinas Treatment Facility. Currently, the only inflow is industrial wastewater produced by vegetable washing and related agricultural processing facilities in Salinas (agricultural wash water). The only outflows are evaporation and percolation. Under the proposed GWR Project, agricultural wash water would only be sent to the Salinas Treatment Facility during November-April, when irrigation demand is low. During May-October, it would be sent directly to the RTP for immediate treatment, and recycling. In addition, water stored in the Salinas Treatment Facility ponds over the winter would be pumped out and sent to the RTP. Finally, stormwater runoff from the southern part of Salinas would be added as a new source of inflow to the Salinas Treatment Facility ponds. Monthly water balances showing inflows and outflows to and from the Salinas Treatment Facility under existing conditions and with the GWR Project are presented in the following sections.

## 2. 2013 Salinas Treatment Facility Operations (Existing Conditions)

The water balance of the Salinas Treatment Facility during 2013 was quantified as the starting point for evaluating potential impacts. A water balance is a detailed tabulation of inflows, outflows and storage changes for a defined hydrologic system. In this case, flows and storage changes were calculated monthly. Extra measurements of flow and quality in the Salinas River near the Salinas Treatment Facility during 2013 supported calculations related to the fate of water that percolated from the ponds. Salinas Treatment Facility operations during 2013 differed from “existing conditions” for CEQA purposes in two respects. First, 2013 was an extremely dry year, which resulted in atypical net pond evaporation. Second, inflows to the Salinas Treatment Facility have been increasing in recent years and the amount of agricultural wash water sent to the Salinas Treatment Facility is projected to continue increasing in the future. Another potentially appropriate definition of baseline conditions for CEQA purposes would include inflows at the time the GWR Project goes on-line (assumed here to be 2017) and average rainfall and evaporation. That condition is described in Section 4, below. Both the existing conditions (represented as the 2013 conditions) and this future baseline are used in the analysis of impacts to thoroughly comply with the requirements of CEQA.

A diagram of flow routing among the Salinas Treatment Facility ponds is shown in **Figure 2** (City of Salinas; Operations and Maintenance Manual, January 30, 2003; recreated by DD&A and Todd

[1] The area proposed for use of the purified water is the Monterey District service area of the California American Water Company.

Groundwater, February 2014). In 2013, all agricultural wash water was sent to the Salinas Treatment Facility, and those flows were metered upon arrival. During the past ten or more years, the percolation ponds have been continuously full or nearly so, which has precluded normal maintenance activities such as drying and disking the pond bottoms. Consequently, percolation rates in Ponds 1-2-3 have declined (Margaretten, 2013). The ponds are approximately flat-bottomed and 6-10 feet deep, which means that pond surface area remains relatively constant over most of the range of storage volumes.

**Table 1** presents a monthly water balance for the ponds and drying beds during 2013. Entries in the table are shown to three or four significant digits for arithmetic consistency. However, estimates of evaporation and percolation are probably accurate to only two significant digits. Accordingly, percolation and evaporation values extracted from the table are rounded in the text to two significant digits or the nearest 10 acre-feet. Agricultural wash water inflow totaled 3,240 acre-feet (AF) during 2013. Monthly rainfall is from the Salinas municipal airport station and is the same data used for urban runoff calculations in the Salinas River Inflow Impacts Report (Schaaf & Wheeler 2015). Annual rainfall during calendar year 2013 was 3.3 inches, or 25 percent of the 1932-2013 average, making it the driest year in the 81-year period of record. The rainfall rate was multiplied by the combined area of all the ponds (118.4 acres) to obtain the volume of rainfall accretion to pond storage. Rainfall added about 50 AF to the ponds in 2013 but would add 200 AF in a year with normal rainfall. Evaporation was similarly estimated from CIMIS reference evapotranspiration data.[2] Pond evaporation totaled 390 AF in 2013 and would be 360 AF in an average year.

The volumes of water spread on the drying beds are not recorded. Due to poor drainage, 13 of the drying bed cells are not used, which corresponds to roughly one-fourth of the 67-acre drying bed complex (Cole, 2014). Due to capacity constraints at the Salinas Treatment Facility, the remaining 75 percent of the drying bed area was more or less continuously wet throughout the year (Cole 2014c), and it was assumed that the per-area evaporation rate equaled the pond evaporation rate. Pond water levels are also not routinely monitored. It was assumed that the net change in storage over the year was zero, given that the facility has been operating near capacity and that excess inflow is handled using the drying beds and RIBs rather than by a long-term increase in pond storage. Finally, the overall percolation volume was obtained as the residual in the water balance and totaled 2,730 AF in 2013. The residual is the amount of percolation that in combination with all other inflows and outflows resulted in a calculated net storage change of zero from December 2012 to December 2013. The percolation rate from the ponds was assumed to be equal in all months.

---

[2] Reference evapotranspiration is typically about 75 percent of open-water evaporation from a Class A evaporation pan (Dunne and Leopold, 1979). However, evaporation from lakes is also less than pan evaporation because the larger surface area causes the adjacent air layer to become more saturated with moisture. The pan-to-lake coefficient is also typically about 75 percent, so evaporation from the ponds—which are the size of small lakes—can be approximated by reference evapotranspiration.

**Table 1. Monthly Salinas Treatment Facility Water Balance during 2013**[3]

| Month | Agri-cultural Wash Water Inflow (AF) | Rainfall Rate (in) | Rainfall Volume (AF) | Pond Evaporation Rate (in) | Pond Evaporation Volume (AF) | Drying Bed Evaporation (AF) | Pond + RIB + Drying Bed Percolation (AF) | Pond Storage (AF) |

| Oct-13 | 355 | 0.15 | 2 | 3.10 | 31 | 13 | 227 | 1,122 |
| Nov-13 | 284 | 0.47 | 7 | 1.99 | 20 | 8 | 227 | 1,159 |
| Dec-13 | 193 | 0.21 | 3 | 1.95 | 19 | 8 | 227 | 1,100 |
| Total (AF): | 3,231 | 3.26 | 50 | 39.34 | 388 | 165 | 2,729 | |
| Percent of SIWTF outflow: | | | | | 12% | 5% | 83% | |

Notes: AF = acre-feet; RIB = rapid infiltration basin; Ponds 1-2-3 + RIB area = 106 acres; drying bed area = 67 acres; average percolation rate = 0.043 feet per day; aeration pond area = 12.4 acres, which is included in rain and evaporation but not percolation.

A key result of the water balance analysis is that only 17 percent of Salinas Treatment Facility outflow was by evaporation at the ponds and drying beds during 2013. Therefore, it can be concluded that percolation is the primary means of wastewater disposal at this facility.

[3] Volumes in the table are shown in units of acre-feet (AF), which is customary for analysis of groundwater flow. The corresponding rates are acre-feet per month (AF/mo) or per year (AFY). Water and wastewater studies typically express volumes and rates in million gallons (mgal; 1 mgal = 3.069 AF) and million gallons per day (mgd). River flows are usually expressed in cubic feet per second (cfs; 1 cfs = 725 AFY = 0.65 mgd). This memorandum uses whichever units are customary for the topic under discussion.

## 3. FATE OF SALINAS TREATMENT FACILITY PERCOLATION WATER

Water that percolates from the Salinas Treatment Facility ponds travels through the subsurface using two pathways: a short path from beneath the ponds to the Salinas River and a longer flow path into the shallow aquifer away from the river. These pathways are part of a complex three-dimensional groundwater flow system that interacts dynamically with water levels in the river and the Salinas Treatment Facility ponds. This system is portrayed in **Figure 3**, which shows a cross-section through the Salinas Treatment Facility perpendicular to the river (see Figure 1 for cross section location). In addition to water levels in the ponds and river, groundwater levels are shown for two of the eight onsite monitoring wells. These wells monitor the shallow aquifer, which is discontinuously present and overlies the Salinas Valley Aquitard, which is a fine-grained layer that restricts downward flow of water from the shallow aquifer to the 180-Foot aquifer. The 180-Foot aquifer is the shallowest aquifer used for water supply in the Salinas region. As its name implies, it is typically present at depths of approximately 180 feet below ground surface. It is underlain by the 400-Foot and deep aquifers, which are also used for water supply. Intervening fine-grained layers restrict flow between the aquifers. An average water level is shown on the figure for nearby wells that are screened in the 180-Foot aquifer. The water surface elevations of the ponds are higher than the water surface of the river and shallow aquifer, and all three are higher than water levels in the 180-Foot aquifer. Pond percolation creates a water-table mound that sends groundwater in all directions. Because the river is only 200 feet from the ponds along the entire 1.5-mile length of the Salinas Treatment Facility and has a much lower water surface, a substantial percentage of percolated water is likely to flow to the river. Percolated water that disperses into the shallow aquifer is likely to percolate down to the 180-Foot aquifer (see Section 3.2 “Recharge to the Shallow and 180-Foot Aquifers”, below).

These water-level relationships can also be seen in **Figure 4**, which shows hydrographs of daily water levels measured in eight monitoring wells at the Salinas Treatment Facility site during 2009-2012 (see Figure 1 for well locations). The plot also includes a hydrograph of water level in the Salinas River, which was estimated from daily flow recorded at the USGS gage at Spreckels (2.5 miles upstream of the Salinas Treatment Facility) and the flow-stage rating curve for that gage. Stream elevations were projected to the Salinas Treatment Facility location based on the average gradient of the river channel and were consistent with elevations determined from Google Earth. Several high-flow events can be seen in the hydrographs. Water levels in the two wells on the river side of Ponds 1-3 (wells MW-1 and MW-2) track river stage closely. Monitoring wells on the far side of the ponds (wells MW-3, -4, -5 and -6) have relatively stable water levels 12-15 feet higher than the river that show little response to fluctuations in river stage. This pattern confirms that shallow groundwater in close proximity to the river is hydraulically connected to flow in the river. Water can readily flow from the aquifer into the river or vice versa, depending on which is higher, the surface of the river or the water table. The pattern also confirms that pond percolation is the dominant influence on groundwater levels in areas on the far side (northeast) of the ponds. This is expected given that the ponds are 10-15 times wider than the river.

### 3.1 Seepage into the Salinas River

The subsurface flow of pond percolation into the river (seepage) is not routinely measured. However, two sets of measurements were made in October and November, 2013. These used two different methods:

- **Water quality mixing model**. MRWPCA personnel measured water quality in the Salinas Treatment Facility ponds and in the Salinas River at points upstream and downstream of the ponds on October 8, 2013. At that time, pond water was high in chloride (Cl) relative to the river. Chloride is a conservative solute that tends to remain in solution without reacting, adsorbing or precipitating. It is commonly used in mixing model calculations. By comparing the increase in chloride concentration in river water along the Salinas Treatment Facility reach, the amount of seepage from the ponds into the river can be calculated. This approach uses a mixing model represented by the following equation:

$$Q_1C_1 + Q_2C_2 = Q_3C_3$$

where,

$Q_1$ = river flow upstream of Salinas Treatment Facility
$C_1$ = concentration in river upstream of Salinas Treatment Facility
$Q_2$ = percolation from ponds toward the river
$C_2$ = concentration in ponds
$Q_3$ = river flow downstream of Salinas Treatment Facility
$C_3$ = concentration in river downstream of Salinas Treatment Facility

Using the concentrations $C_1$, $C_2$ and $C_3$ measured on October 8, 2013, the value of $Q_1$ measured at the Spreckels stream gage on that date, and noting that $Q_3 = Q_1 + Q_2$, the mixing model can be solved to obtain $Q_2$, which is the rate of subsurface flow from the ponds into the river. The variables are listed in **Table 2**, and the calculated estimate of seepage from the ponds to the river was 3.67 cfs.

Transpiration by riparian vegetation between the ponds and river does not materially affect the calculations. The vegetation transpires essentially pure water, but correcting for this loss only slightly changes the calculations. The strip of riparian vegetation between the RIBs and the river channel averages 175 ft wide and has a total area of 31.5 acres. Multiplying that area by the reference ET rate measured at the CIMIS station in Salinas on October 8, 2013 (0.10 inches) results in an estimated 0.13 cfs of water consumption. In terms of the above system of equations, $Q_3 = Q_1 + Q_2 – Q_{ET}$. Conservatively assuming that all of the evapotranspiration is of pond percolation and none is of river underflow, the resulting estimate of pond percolation becomes 3.72 cfs. The initial and adjusted estimates differ by only 1.3 percent, which is less than the uncertainty in other factors in the equation. For practical purposes, the effect of water loss to evapotranspiration can safely be ignored.

**Table 2. Variables Used for Chloride Mixing Model Calculation of Subsurface Flow of Salinas Treatment Facility Pond Seepage into the Salinas River**

| Parameter | Value | Units |
|---|---|---|
| $Q_1$ = | 15 | cfs |
| $C_1$ = | 26 | mg/L |
| $Q_2$ = | $Q_2$ | cfs |
| $C_2$ = | 292 | mg/L |
| $Q_3$ = | 15 + $Q_2$ | cfs |
| $C_3$ = | 79 | mg/L |

- **Change in river flow**. River flow at Salinas Treatment Facility is usually at its annual minimum in November, after upstream reservoir releases have ceased and before natural rainfall runoff has commenced. Those conditions are optimal for direct measurement of seepage derived from pond percolation, which is only a small percentage of total flow at other times of the year. River flow upstream and downstream of the Salinas Treatment Facility was measured on November 13, 2013. Visual inspection revealed that flow was zero upstream of Davis Road, although pools were still present in the channel. Flow was measured using a propeller-type ("pygmy") flow meter 1,000 ft downstream of Pond 3, which produced a value of 2.4 cfs. The accuracy of the measurement was probably only +/- 20% due to deep, low-velocity conditions. However, this result was similar to the estimate from the mixing model.

For the purposes of the SIWTF percolation analysis in this memorandum, the two estimates of seepage into the river were simply averaged, with a resulting estimate of 3.0 cfs. If this rate were constant throughout the year, it would amount to 2,170 AFY, or 80 percent of total SIWTF pond percolation during 2013. This percentage is expected to remain approximately the same with the higher expected SIWTF inflow in 2017, provided that the RIBs and drying beds continue to be operated in the present manner.

There are several sources of uncertainty in estimating the future effects of SIWTF pond percolation on river flows. First, the operators of the SIWTF have flexibility to modify their operations in ways that might influence the relative proportions of seepage into the river and percolation that flows downward to the 180-Foot aquifer. For example, if percolation is shifted from the RIBs back to Ponds 1, 2 and 3 (assuming percolation rates in one or more of those ponds were restored by drying and disking) or to the drying beds, then the center of percolation would shift slightly away from the river, and the proportion of percolation that goes to the 180-Foot aquifer could increase. Such future changes are outside the control of the GWR Project. Reservoir releases to the Salinas River could also change in the future in response to evolving water demands along the Salinas Valley or changes in seawater intrusion near the coast. Finally, climate change could impact seasonal runoff patterns, average annual rainfall and runoff, and the yield of upstream water supply reservoirs.

### 3.2 Recharge to the Shallow and 180-Foot Aquifers

By ruling out other potential pathways, it can be concluded that percolation from the Salinas Treatment Facility to the shallow aquifer that does not seep to the Salinas River percolates downward and becomes recharge to the 180-Foot aquifer. Other outflow pathways that were considered and rejected included:

- **Evapotranspiration by phreatophytic vegetation.** Phreatophytes are plants such as willow, cottonwood and sycamore with roots that can extract water directly from the water table. They are common along rivers and other shallow water-table areas in California. No phreatophytes are present in the cropland north and east of the Salinas Treatment Facility. A band of phreatophytes is present along both sides of the Salinas River channel downstream of Spreckels. The width, stature and vigor of the riparian vegetation between the Salinas Treatment Facility and the river are no different than on the opposite bank or along upstream and downstream reaches. Therefore, from a water balance standpoint, the riparian vegetation is supplied by shallow groundwater associated from the river, and riparian evapotranspiration does not constitute a separate outflow pathway from the Salinas Treatment Facility.

- **Passive seepage into Blanco Drain.** Blanco Drain is a ditch that conveys agricultural drainage water from a 6,400-acre area to the Salinas River. The Drain approximately parallels the river about 1.2 miles northeast of the Salinas Treatment Facility, which is 37 times farther from the Salinas Treatment Facility than the river channel is. The Drain is also shallower than the river channel. Therefore, it is not hydraulically plausible that recharge at the Salinas Treatment Facility would flow to the Drain instead of the river.

- **Active removal by agricultural tile drains.** Agricultural tile drains are parallel rows of perforated pipe buried several feet beneath the ground surface over the entire area of certain fields to prevent the crop root zone from becoming waterlogged. The pipes drain to a sump, where the water is pumped up into a ditch that carries it away. Tile drains are common in the Blanco Drain watershed—which includes the Salinas Treatment Facility site—and the primary purpose of Blanco Drain is to convey tile drain discharge to the Salinas River. The source of the water that causes the soil saturation problem can be either a shallow water table—such as one receiving excess recharge from Salinas Treatment Facility percolation—or applied irrigation water that cannot percolate downward through the root zone due to restrictive layers in the soil horizon. In the former case, drain discharges would be greatest in spring, following winter rainfall recharge of the shallow aquifer. In the latter case, discharges would be greatest during the peak of the irrigation season. Measured monthly flows in Blanco Drain peak in July at a level two times greater than the minimum monthly flow in November (Schaaf & Wheeler 2015). This seasonal pattern suggests that the primary source of the drainage water is applied irrigation water, not a shallow water table caused by Salinas Treatment Facility percolation.

- **Subsurface flow through the shallow aquifer, parallel to the river with eventual discharge into the Salinas River lagoon or Monterey Bay.** This flow is negligible because the shallow aquifer is patchy and discontinuous (Kennedy/Jenks Consultants, 2004), the distances to those discharge points are large, and the hydraulic gradients are correspondingly low. Groundwater flow is proportional to the water-level gradient, which is the difference in potentiometric head[4] at two points in a groundwater flow system divided by the distance between the points. The gradient from the water table beneath the Salinas Treatment Facility ponds downward to the 180-Foot aquifer is about 0.24 foot per foot (ft/ft). By comparison, the Salinas River lagoon and Monterey Bay are 6-8 miles away, and water-level gradients between the Salinas Treatment Facility and those locations range from 0.0007 ft/ft to 0.0008 ft/ft. These are about 300 times smaller than the downward gradient to the 180-Foot aquifer. The cross-sectional area available for downward flow is also about two orders of magnitude larger than for horizontal flow through the shallow aquifer, assuming the shallow aquifer were continuous to the lagoon and ocean. However, the discontinuous pattern of shallow aquifer deposits overlying the Salinas Valley Aquitard greatly diminish the cross-sectional area available for flow and increase the length of the flow path. These factors favoring downward over horizontal flow very likely outweigh the lower average permeability in the downward direction.

- **Underflow through Salinas River channel deposits.** Permeable sand deposits are present beneath and adjacent to the river channel, at least in places. Anecdotal evidence of these deposits include the high percolation rates of the rapid infiltration basins adjacent to the channel at the Salinas Treatment Facility and the high rate of dewatering pumping that was required during construction of the Salinas River Diversion Facility and a pipeline crossing beneath the river. The underflow through sand deposits can be estimated by applying the Darcy equation using estimates of cross sectional area, hydraulic conductivity and gradient. Assuming a continuous body of sand extending to 15 feet below the water surface and to 100 feet on either side of the channel center line, with a typical hydraulic conductivity for clean sand of 100 feet per day (Freeze and Cherry, 1979), and a gradient along the river of 0.0008 feet per foot, then the subsurface flow would be 240 cubic feet per day, which is equivalent to 0.003 cubic feet per second, or one-thousandth the estimated amount of seepage from the Salinas Treatment Facility ponds to the river. Thus, over long distances, one thousand times more water would travel as surface flow than as underflow. This result does not contradict the anecdotal observations; the key difference is the long flow path and small hydraulic gradient. Over shorter flow paths—such as from the rapid infiltration basins to the river or from the river to nearby dewatering wells—the amount of subsurface flow can be significant.

To reach the 180-Foot aquifer, groundwater in the shallow aquifer must flow downward through the Salinas Valley Aquitard (SVA). The SVA is a shallow fine-grained layer that has traditionally been viewed as an extensive, continuous, impermeable clay cap that restricts direct downward recharge to the 180-Foot aquifer. Water levels in the 180-Foot aquifer are much lower than shallow groundwater levels, which suggests that overall vertical permeability is low but not necessarily zero. In 2011, groundwater elevation in the 180-Foot aquifer near Salinas Treatment Facility was -18 ft (i.e., below sea level), while

[4] Potentiometric head is represented by the water level in a well that is screened at a point within the flow system. In this case, the water level in a well screened at the water table beneath the Salinas Treatment Facility ponds would be about 30 ft above sea level, while the water level in a well at the same location screened in the 180-Foot aquifer would be about 18 ft below sea level.

water levels in shallow wells near the ponds were 12-33 ft above sea level. This substantial downward gradient will induce downward flow if permeable pathways are present.

Evidence that recharge occurs through the SVA comes from detailed stratigraphic analyses and groundwater model calibration. One of the most detailed evaluations of aquifer stratigraphy in the vicinity of the Salinas Treatment Facility focused on the area encompassed by Alisal Slough, Highway 68 and the Salinas River, which includes the Salinas Treatment Facility (Heard, 1992). Texture descriptions from 117 cable-tool driller's logs were classified into coarse and fine categories and mapped at 20-foot depth intervals from the ground surface down to 340 feet. Overlaying these maps reveals vertical continuity of coarse deposits through all but one of the top seven layers (a total vertical interval of 140 feet) in several locations, each covering about 1 square mile:

- Near the Salinas Treatment Facility across South Davis Road
- Near the intersection of Blanco Road and Highway 68, about 2.5 miles east of the Salinas Treatment Facility
- Along Davis Road between Blanco Road and Castroville Road, about 2.5 miles northeast of the Salinas Treatment Facility

A small amount of horizontal flow within the remaining depth interval would allow groundwater flow to link up gaps between clay lenses and continue moving downward.

Heard also evaluated groundwater quality patterns and discovered that groundwater in the 180-Foot aquifer in the study area was slightly enriched in sulfur relative to other dissolved minerals. The only geochemically plausible source of the enrichment was determined to be gypsum, which is commonly applied to heavy soils in the area to maintain soil texture. To arrive at the 180-Foot aquifer, the dissolved gypsum would have had to percolate downward through the SVA. Nitrate is also elevated in some 180-Foot aquifer wells in the area and also derives from fertilizers applied at the land surface.

Another detailed stratigraphic study of the region between Spreckels and the coast included cross sections showing the SVA missing at various locations (Kennedy/Jenks Consultants, 2004). The cross sections were developed from geologic logs prepared by well drillers, and most of the logs were from irrigation wells. Although often close to other wells where the SVA is present, wells that show gaps in the SVA include several near the Salinas Treatment Facility in the region between Salinas and the Salinas River (at wells APN-414021010, 15S/03E-04T50, 15S/03E-17B3, and 15S/03E-17M1). The description of SVA hydrogeology in the Monterey County Groundwater Management Plan reiterates the concept of local discontinuity (MCWRA 2006).

A groundwater flow model of the Salinas Valley, called the Salinas Valley Integrated Surface and Groundwater Model (SVISGM), has been used extensively by Monterey County Water Resources Agency (MCWRA) for water planning studies over nearly 20 years. The calibrated model includes recharge from the ground surface to the 180-Foot aquifer. The 180-Foot aquifer is present only in the Pressure Area, which occupies the southwestern half of Salinas Valley between Gonzales and Monterey Bay. In most parts of the Pressure Area, recharge to the 180-Foot aquifer from the ground surface would have to pass through the SVA (MWH, 1997). The shallow aquifer and SVA are not explicitly represented in the model, but their effects are reflected in the amount of downward recharge that accrues to the 180-Foot aquifer. During the 1970-1994 calibration period, there was an average of 54,000 AFY of recharge to the 180-Foot aquifer in the Pressure Area from deep percolation of rainfall and applied irrigation water and 60,000 AFY of recharge from Salinas River infiltration, some of which must also pass through the SVA. Together, these recharge sources accounted for 79% of total recharge to the 180-Foot aquifer in the Pressure Area. However, much of the downward recharge to the 180-Foot aquifer in the model could have been in the southern part of the Pressure Area (between Gonzales and Chualar), where the SVA is known to be discontinuous or absent.

The above lines of evidence lead to a conclusion that Salinas Treatment Facility percolation that does not seep into the river very likely becomes recharge to the 180-Foot aquifer. During 2013, this recharge amounted to 550 AF, or 20% of total Salinas Treatment Facility percolation.

## 4. FUTURE NO-PROJECT SALINAS TREATMENT FACILITY WATER BALANCE

The 2013 Salinas Treatment Facility water balance described in Section 2 was not representative of existing or no-project conditions for the purpose of evaluating impacts. Rainfall was extremely low that year, and inflows of agricultural wash water were less than the inflows expected at the time the GWR Project is constructed. A more appropriate baseline for evaluating impacts is the Salinas Treatment Facility water balance under normal climatic conditions and with the inflows expected to occur in 2017 (the approximate date of construction). This is consistent with the Salinas River Inflows Impact Report (Schaaf & Wheeler 2015), which evaluated 2017 Salinas Treatment Facility inflows and normal climatic conditions.

The estimated baseline (no-project) Salinas Treatment Facility water balance is shown in **Table 3**. Agricultural wash water inflows are expected to total 3,730 in 2017. Monthly rainfall and evaporation rates are long-term averages for stations in Salinas. As in the 2013 water balance (see Table 1), it was assumed there would be no net increase in pond storage over the year. The assumed percolation rate was increased to achieve zero net storage change, and the relative proportions of seepage to the river and percolation to groundwater are the same as in the 2013 water balance. The resulting estimate of seepage into the river is 2,730 AFY, and the estimate of percolation to the 180-Foot aquifer is 680 AFY.

**Table 3. Monthly Baseline (No-Project) Salinas Treatment Facility Water Balance**

| Month | Agri-cultural Wash Water Inflow (AF) | Rainfall Rate (in) | Rainfall Volume (AF) | Pond Evaporation Rate (in) | Pond Evaporation Volume (AF) | Drying Bed Evaporation (AF) | Pond + RIB + Drying Bed Percolation (AF) | Pond Storage (AF) |
|---|---|---|---|---|---|---|---|---|
| DEC | | | | | | | | 1,100 |
| JAN | 156 | 2.62 | 40 | 1.21 | 12 | 5 | 285 | 995 |
| FEB | 158 | 2.35 | 36 | 1.54 | 15 | 6 | 285 | 883 |
| MAR | 201 | 2.11 | 33 | 2.88 | 28 | 12 | 285 | 791 |
| APR | 307 | 1.10 | 17 | 4.08 | 40 | 17 | 285 | 773 |
| MAY | 311 | 0.30 | 5 | 4.56 | 45 | 19 | 285 | 740 |
| JUN | 391 | 0.08 | 1 | 5.16 | 51 | 22 | 285 | 775 |
| JUL | 435 | 0.02 | 0 | 4.47 | 44 | 19 | 285 | 863 |
| AUG | 444 | 0.04 | 1 | 4.30 | 42 | 18 | 285 | 962 |
| SEP | 367 | 0.17 | 3 | 3.20 | 32 | 13 | 285 | 1,002 |
| OCT | 410 | 0.57 | 9 | 2.75 | 27 | 12 | 285 | 1,098 |
| NOV | 329 | 1.41 | 22 | 1.50 | 15 | 6 | 285 | 1,143 |
| DEC | 223 | 2.35 | 36 | 1.23 | 12 | 5 | 285 | 1,100 |
| Total (AF): | 3,732 | 13.12 | 203 | 36.88 | 364 | 154 | 3,416 | |
| Percent of SIWTF outflow: | | | | | 9% | 4% | 87% | |

Notes: AF = acre-feet; RIB = rapid infiltration basin; Ponds 1-2-3 + RIB area = 106 acres; drying bed area = 67 acres; wash water inflows are the expected amounts in 2017; rainfall and evaporation are long-term averages; percolation rate = 0.054 feet per day; aeration pond area = 12.4 acres, which is included in rain and evaporation but excluded from percolation.

## 5. LOCAL HYDROLOGIC EFFECTS OF THE GWR PROJECT

The GWR Project would alter the operation of the Salinas Treatment Facility in terms of the amounts and types of water stored at the facility. Those changes would locally alter the quantity and quality of percolation, which would affect the quantity and quality of river flow and groundwater recharge. This memorandum focuses on local effects. However, those effects should be considered in a regional context because surface and groundwater throughout the northern Salinas Valley area are intensively managed as a single, interconnected system. Effects on operation and yield of the Salinas Valley Water Project are described in the Salinas River Inflow Impacts Report (Schaaf & Wheeler 2015). The combined effects of all elements of the GWR Project on regional groundwater pumping and seawater intrusion are described in Chapter 4 of the DEIR. Potential local hydrologic impacts evaluated in this memorandum are the following:

- Changes in Salinas River flow
- Decreased groundwater recharge and local well yields
- Changes in river and groundwater quality

All of these impacts stem from changes in the amount of water percolated at the Salinas Treatment Facility. Accordingly, the first step in the impact analysis is to calculate the amount of percolation by month and year type for each potential example scenario of operation of the GWR Project (see Section 5.2 for a description of these scenarios). This depends in part on the distribution of percolation among the various ponds, basins and drying beds at the Salinas Treatment Facility.

### 5.1 Percolation Patterns at the Salinas Treatment Facility

Water percolates from Ponds 1, 2 and 3, the RIBs and the drying beds, but percolation rates vary substantially among those areas. Therefore, percolation under existing and project conditions must be estimated for each area separately to the extent available data support such an analysis. The aeration pond is lined and percolation is assumed to be negligible. Percolation from Ponds 1-2-3 historically declined due to accumulation of fine-grained material and/or biofilms on the pond bottoms. As annual inflows increased, the ponds no longer drained completely at any point during the year, which prevented the normal maintenance procedure of drying and disking the pond bottoms to restore percolation rates (Margaretten, 2013). This led to reliance on the RIBs and drying beds to provide additional disposal capacity during the past decade. The drying beds have actually been operated more like percolation basins in recent years. Low berms divide the drying bed area into 54 cells or beds separated by low berms. Each bed is flooded to a depth of 1.0-1.5 feet then allowed to percolate, which takes anywhere from 5 days to several weeks (Cole, 2014c). The three RIBs are long, narrow basins that occupy a strip along the river side of Ponds 1-2-3. They have consistently provided relatively high rates of percolation but cover only a small area. Unfortunately, available records for Salinas Treatment Facility operations do not document the volumes of water sent to each of the three areas; only the total amount is known. However, soils information and semi-quantitative anecdotal data can be used to estimate the amounts percolated at each area during 2013 and/or 2014, as follows:

- **Percolation at RIBs.** Two methods were used to estimate percolation rate: the rate at which water was pumped into the RIBs and the time required for them to drain. The two diesel-powered pumps that transferred water from Ponds 1, 2 and 3 to the RIBs operated 1,000 hours each at an estimated discharge of 800 gallons per minute (Cole, 2014c). These figures produce an estimate of 300 AF pumped during the year. However, the pump discharge was estimated from its rated capacity under 150 feet of lift, whereas the actual lift was about -10 feet (the pumps were moving water downhill from the ponds to the RIBs). Consequently, the actual discharge rate was probably higher. After drying and disking, each RIB would drain in 2-3 days; however, percolation rates decreased noticeably as the season of use progressed (Cole, 2014c). A decrease in percolation rate due to clogging of the bed with fine-grained material or organic biofilms is a nearly universal occurrence in percolation basins operated for prolonged periods. The long-term average percolation rate assuming periodic disking and drying typically averages about 25 percent of the initial percolation rate (Bouwer, 1985; Schuh and Shaver, 1989; Miele, 2011). Assuming a ponding depth of 2 feet and 10-day average percolation cycle, the combined 1.67 acres of RIBs would percolate 120 AF per year. This estimate is considerably smaller than the pump-operation estimate. The resulting range of plausible RIB percolation volume during 2013 is roughly 100-400 AF.

- **Percolation at drying beds.** Percolation rates are highly variable among the drying bed cells and appear to be influenced by soil variability, season, and depth to the underlying water table (Cole, 2014c). Individual beds are flooded to a depth of 1.0-1.5 feet then allowed to completely infiltrate, which takes anywhere from 5 days to many weeks. About 18 of the beds percolate only once per season or not at all. Thus, the long-term average percolation rate is about 1.25 foot over 20-100 days. Assuming year-round operation over the 67-acre drying bed area, annual percolation is roughly 200-1,400 AFY (after subtracting 130 AFY of normal-year net evaporation).

- **Percolation from Ponds 1, 2 and 3.** The percolation rate from Ponds 1-2-3 can estimated from the observed change in storage during spring 2014, when all inflows to the Salinas Treatment Facility were diverted to the Regional Treatment Plant. Based on manual readings of staff gages in the three ponds, water levels declined 4.5-5.5 feet during April and May, 2014. Water was being pumped from those ponds to the drying beds and RIBs throughout that period, so percolation at Ponds 1-2-3 equaled the change in storage minus percolation at the other two facilities and minus net evaporation from all of the facilities. Net evaporation over 173 acres of wetted area was 150 AF, which leaves 380 AF of the total storage change attributable to percolation. To be consistent with the annual percolation rate estimated for 2013, this 2-month estimate of percolation during April-May, 2014 was increased 20 percent to 460 AF. Percolation at the RIBs during the two months probably equaled one-sixth of the annual percolation during 2013, or 17-67 AF. Percolation from the drying beds can similarly be estimated as one-sixth of the 2013 annual percolation volume, or 33-230 AF. Subtracting the minimums and maximums of these percolation ranges from the total percolation volume produces an estimated range of Pond 1-2-3 percolation of 160-400 AF. Using the midpoint of that range as an estimate of the average results in 280 AF of estimated percolation during April-May, which is equivalent to an annual rate of 1,680 AFY or 140 AF per month. Based on the above information regarding percolation at the individual facilities, Ponds 1-2-3 account for 62% of total percolation when all three facilities are in operation, the RIBs account for 9%, and the drying beds account for 29%.

  A lower estimate of the percolation rate for Ponds 1-2-3 is obtained if the 2014 results are not adjusted to be consistent with the 2013 results. In that case, the percolation rate is 103 AF per month.

### 5.2 Decreased Groundwater Recharge and Local Well Yields

A spreadsheet operations model was developed to estimate which source waters would be selected for the GWR Project under six operating scenarios: two phases of diversion rate for surface water sources and three types of years related to the status of the drought reserve (See the Draft EIR Project Description Section 2.7.1 for a description of the source water availability and assumed diversion scenarios). The model indicated the amount of water sent to or pumped from the Salinas Treatment Facility for each month of the year. The model was based on two unique sets of monthly inflows and outflows: in normal/wet years and in drought years. Simulated Salinas Treatment Facility operations were not affected by the maximum surface water diversion rate or the current storage level of the drought reserve.

Some of the water that percolates from the Salinas Treatment Facility flows downward through gaps in the Salinas Valley Aquitard and becomes recharge to the 180-Foot aquifer, which is one of several aquifers tapped by water supply wells in the northern Salinas Valley. A decrease in percolation would decrease recharge and tend to lower groundwater levels in wells near the Salinas Treatment Facility that pump from the 180-Foot aquifer. If the decline in water levels were large, it could impact groundwater availability to well owners by physically damaging wells or by decreasing their pumping rates. Quantifying that impact begins with estimating the decrease in percolation from the Salinas Treatment Facility that would result from the GWR Project.

#### 5.2.1 Change in Percolation Volumes

Operation of the Salinas Treatment Facility would change substantially under the GWR Project. In spite of new inflows of urban storm runoff, total annual inflow would decrease substantially because agricultural wash water inflows would be diverted to the Regional Treatment Plant during half the year for recycling and use by the CSIP irrigators and for advanced treatment and injection into the Seaside Groundwater Basin. The drying beds and RIBs would no longer be needed. The primary purpose of the Salinas Treatment Facility would switch from disposal to storage; any water that does not percolate or evaporate during the November-April storage season would be pumped back out to supply the GWR Project. Only Ponds 1, 2 and/or 3 would be used for storage. The effect of reoperation under the GWR Project depends on the amount of percolation that continues to occur during the storage and pump-out seasons. This can be determined from monthly water balance calculations for the ponds, given the percolation rates estimated above.

**Table 4** shows the monthly pond water balance in normal/wet years, and **Table 5** shows the balance during drought years. Inflows of agricultural wash water and Salinas urban storm runoff were obtained from the Salinas River Inflows Impact Report (Schaaf & Wheeler 2015). The rainfall and evaporation rates in Table 4 are average annual rates, and the rates in Table 5 are the 2013 rates. The percolation rate from Ponds 1-2-3 equals the rate of 140 AF per month estimated from 2014 data adjusted to be consistent with 2013 percolation.

In both tables, the amount of stored water that can be pumped out of the ponds during April-October is limited by percolation losses. Although percolation rates have declined over the past decade, the ponds still retain substantial percolation capacity and hence are not optimal for storage. In the tables, all of the water was assumed to be pumped out during May and June to avoid additional percolation losses that would occur if the stored water were pumped out over a longer period. The amount of water pumped out to supply the GWR Project during May-June would be approximately 380 AF in normal or wet years and 120 AF in dry years. Annual percolation from all Salinas Treatment Facility facilities would be approximately 1,110 AFY in normal and wet years (Table 4), which is 2,300 AFY less than under baseline conditions (Table 3). The proportion of percolated water that seeps into the Salinas River (80 percent) would remain about the same as under baseline conditions because the center of percolation volume would remain under Ponds 1-2-3. That is, the two percolation facilities that would be discontinued (RIBs and drying beds) are closer and farther from the river, respectively, than Ponds 1-2-3. Therefore, seepage into the river would be approximately 890 AFY (1.2 cfs), and recharge to the 180-Foot aquifer would be approximately 220 AFY.

## Table 4. GWR Project Salinas Treatment Facility Water Balance in Normal/Wet Years

| Month | Agricultural Wash Water (AF) Total Available | Agricultural Wash Water (AF) Sent to STF | Salinas Urban Storm Water Inflow (AF) | Rainfall Rate (in) | Rainfall Volume (AF) | Pond Evaporation Rate (in) | Pond Evaporation Volume (AF) | Pumped Outflow to RTP (AF) | Ponds 1-2-3 Percolation (AF) | Pond Storage (AF) |
|---|---|---|---|---|---|---|---|---|---|---|
| DEC | | | | | | | | | | 353 |
| JAN | 156 | 156 | 52 | 2.62 | 25 | 1.21 | 12 | 0 | 140 | 435 |
| FEB | 158 | 158 | 41 | 2.35 | 23 | 1.54 | 15 | 0 | 140 | 502 |
| MAR | 201 | 201 | 34 | 2.11 | 20 | 2.88 | 28 | 0 | 140 | 590 |
| APR | 307 | 307 | 16 | 1.10 | 11 | 4.08 | 40 | 0 | 140 | 745 |
| MAY | 311 | 0 | 2 | 0.30 | 3 | 4.56 | 44 | 190 | 140 | 376 |

| Percent of SIWTF outflow: | | | | | | | 17% | 8% | 75% | |

Notes: AF = acre-feet; RIB = rapid infiltration basin; ponds 1-2-3 area = 104.3 acres; drying beds and RIBs inactive; wash water inflows are the expected amounts in 2017; rainfall and evaporation are 2013 values; ponds 1-2-3 percolation rate = 0.044 feet per day; aeration pond area = 12.4 acres, which is included in rain and evaporation but not percolation.

Percolation from the Salinas Treatment Facility would be more seasonally variable than under baseline conditions. The maximum change in percolation would occur during July-October, when percolation would be zero. Seepage into the Salinas River follows a short subsurface flow path that would respond quickly to changes in percolation. Thus, during July-October, seepage into the river would decrease by 3 cfs. During November-June, seepage into the river would be about 1.9 cfs, or about 1.1 cfs less than under baseline conditions. In drought years, annual percolation would decrease by about 2,230 AFY. Monthly river flow would decrease by 1.1-3.0 cfs depending on the month (same as in normal/wet years), and the annualized average decrease would be 2.5 cfs.

Recharge to the 180-Foot aquifer might also vary somewhat seasonally, but by less than the variations in pond percolation. This is because the relatively low average permeability along the downward flow path would tend to smooth out short-term fluctuations in pond percolation. For the purpose of evaluating water supply and well impacts, the change in average annual percolation is a reasonable basis for comparison with baseline conditions.

It would be possible to line the ponds to reduce percolation and maximize the amount of stored water that could be pumped out to supply the GWR Project. This option could theoretically reduce percolation to near zero year-round. Thus, depending on whether Ponds 1-2-3 are modified or left as is, percolation could range from essentially zero to the amounts shown in Tables 4 and 5. The evaluation of impacts on river flow assumes a year-round decrease of 3 cfs, which represents a worst-case scenario as described in the Salinas River Inflows Impact Report (Schaaf & Wheeler 2015).

#### 5.2.2 Uncertainty of Change in Percolation Volumes

The above estimates of percolation from Ponds 1-2-3 under GWR Project operation are subject to substantial uncertainty. The ranges of uncertainty for RIB and drying bed percolation are quite large, and the midpoints of those ranges were used in calculating the “best” estimate of the percolation rate from Ponds 1-2-3. In addition, the resulting percolation rate was increased by 20 percent to make it consistent with annual percolation volumes observed during 2013. The recoverable yield of water stored in Ponds 1-2-3 is quite sensitive to the percolation rate, because percolation occurs throughout the storage and pump-out periods (November to June). To illustrate this sensitivity, plausible alternative estimates of percolation and yield were calculated using the 2014 percolation rate without the 20 percent adjustment. The 2014 estimated percolation rate from Ponds 1-2-3 is 103 AF per month, and the water balance results for GWR Project operation under normal/wet years can be summarized as follows: recoverable storage pumped for GWR Project use during May-June = 620 AF; total percolation = 830 AFY, of which 660 AFY seeps to the Salinas River and 170 AFY recharges the 180-Foot aquifer. During drought years, total annual percolation is only slightly less than during wet/normal years because the duration of pond inundation would be about the same. Recoverable storage would be only about 400 AF, however, due largely to decreased rainfall and stormwater inflows.

### 5.2.3 Change in Groundwater Levels

Compared with baseline conditions (Table 3) annual pond percolation under GWR Project conditions (Table 4) would decrease by 2,300 AFY, of which 460 AFY would be a decrease in recharge to the 180-Foot aquifer. Recharge from Salinas Treatment Facility pond percolation to the 180-Foot aquifer occurs over a broad area due to the low permeability of the SVA. The ponds are 1.5 miles long, and if 460 AFY of recharge is assumed to be distributed uniformly over a circular area with a radius of 1.5 miles, it would raise water levels in the 180-Foot aquifer by approximately 1.3 feet. Conversely, a decrease in percolation by that amount would tend to lower water levels by 1.3 feet.

The median elevation of the top of the screen in the 23 wells used to monitor water levels in the 180-Foot aquifer is 160 feet below sea level (Feeney, 2014). The water level in wells screened in the 180-Foot aquifer near the Salinas Treatment Facility is approximately 18 feet below sea level, or 142 feet above the top of the screen in a typical well. A decline of 1.3 feet would not lower the water level to below the top of the screen. Therefore, the potential impact of interrupted water supply due to screen corrosion or pump failure would not occur.

Performance curves for typical deep-well turbine pumps indicate that a change in water level of 1.3 feet would in most cases decrease the pump output by 3-4 percent (Driscoll, 1986; Goulds Water Technology, 2014). This small decrease in pump output can typically be accommodated by increased pumping duration.

The change in recharge to the 180-Foot aquifer during drought years would be about 420 AFY less than under baseline conditions, which is a slightly smaller impact than during normal and wet years. Impacts on wells would therefore also be less than significant during drought years.

## 5.3 Changes in Salinas River and Groundwater Quality

The effect of Salinas Treatment Facility percolation on water quality in the Salinas River and 180-Foot aquifer depends on the concentrations of individual chemical constituents in the Salinas Treatment Facility ponds compared to existing concentrations and water quality objectives for those receiving waters. **Table 6** compares median concentrations of chloride, nitrate, total dissolved solids (TDS) and phosphorus for each water body. These constituents are present in pond water at concentrations that pose a risk of contamination. Data for the Blanco Drain are used as a surrogate for shallow groundwater, because most of the flow in Blanco Drain derives from soil water at the base of the root zone in agricultural fields, which is pumped into Blanco Drain from agricultural drainage tile systems. The data shown in the table were compiled from various monitoring programs with differing suites of constituents and periods of record. Aquifer-specific data for groundwater quality were not available, and data in the table probably reflect a combination of 180-Foot and 400-Foot aquifer groundwater. In spite of these limitations in available data, the table reveals several large contrasts in water quality conditions that can be used to infer impacts of Salinas Treatment Facility percolation on water quality.

Median concentrations were used because average concentrations are often influenced by skewed distributions (for example, high outliers for nitrate).

## Table 6. Comparison of Water Quality in Salinas Treatment Facility Ponds, Salinas River and Groundwater

| Water Source | Chloride (mg/L) | Nitrate (mg/L as $NO_3$) | Total Dissolved Solids (mg/L) | Phosphorus (mg/L as P) | Notes |
|---|---|---|---|---|---|
| SIWTF Ponds 1-3 | 301 | 20 | 1,090 | -- | Medians of 12 monthly samples during 2013. Total nitrogen converted to nitrate. |
| SIWTF Ponds | 237 | 26 | 1,228 | 27 | Median of six samples collected during July 2013 to February 2014 |
| Salinas River at South Davis Road (upstream of SIWTF) | 70 | 31 | 618 | 0.1 | CCAMP data. Medians of 92-100 samples during 1998-2011. Primarily low-flow data. |
| Blanco Drain[a] | 274 | 292 | 2,003 | <0.1 | Median of monthly samples collected during July 2013-June 2014 for GWR Project source water investigation (Nellor Environmental Associates, 2015). |
| Groundwater | 100 | 9 | 800 | 0.012 | Chloride, nitrate and TDS from GeoTracker GAMA database. Medians of samples from 15-23 well locations between Salinas and the Salinas River. Dates vary. Combination of 180-Foot and 400-Foot aquifers. Phosphorus is the median of 8 samples from the Pressure Area (Kulongoski and Belitz, 2011). |
| Water Quality Objectives | | | | | |
| Salinas River below Spreckels | 250[b] | 6.2-28[c] | 500-1,000[d] | 0.07-0.13[c] | Basin Plan for the Central Coast Region, and CCRWQCB Resolution R3-2013-2008 |
| 180-Foot Aquifer | 250 | 4 | 1,500 | no objective | |

Notes:

CCAMP = Central Coast Ambient Monitoring Program CCRWQCB = Central Coast Regional Water Quality Control Board

GAMA = groundwater ambient monitoring and assessment SIWTF = Salinas Industrial Wastewater Treatment Facility

[a] Blanco Drain data used as a surrogate for shallow groundwater quality, for which direct measurements are not available.

[b] The drinking water standard for municipal use is shown. Agricultural crops can experience "increasing problems" at concentrations ranging from 142 to 355 mg/L.

[c] Dry-season Total Maximum Daily Load objectives for the lower Salinas River.

[d] The lower and upper secondary drinking water standards are shown. Agricultural crops can experience "increasing problems" at electrical conductivity values that correspond to approximately 500-2,000 mg/L of TDS.

Median concentrations of TDS, chloride and phosphorus are higher in the Salinas Treatment Facility ponds than in the Salinas River and all of those constituents plus nitrate exceed the water quality objectives for the river at least occasionally. During periods when essentially all flow downstream of the Salinas Treatment Facility derives from pond seepage—such as was observed in November 2013—there would be little dilution of pond seepage, and water quality objectives in the river would probably not be met. Mixing model calculations can be applied to estimate the amount of river flow needed to dilute the inflow from pond seepage sufficiently to meet the objectives, as follows:

- In the case of chloride, a flow of only 0.85 cfs would be needed, which is exceeded 92 percent of the time when the river is flowing[5].
- For nitrate, the water quality objective cannot be met by dilution because pond water and river water both already exceed the objective. Concentrations in the ponds and river are similar, and they are 0.7-4.2 times greater than the objective.
- The lower objective for TDS is similarly not achievable by dilution, but the upper objective (1,000 mg/L) would be achieved by dilution with a river flow of 1.8 cfs, which is exceeded 79 percent of the time when the river is flowing.
- The phosphorus concentration in the ponds is 210-390 times greater than the water quality objective for the river. The objective would be achieved by dilution only when river flow exceeds 2,700 cfs, which occurs only 5 percent of the time when the river is flowing. However, phosphorus is not a conservative solute during subsurface transport. It is removed from soil water and groundwater by adsorption and chemical precipitation, which are influenced by pH, dissolved oxygen and the presence of iron, aluminum and calcium. Also, the capacity to remove phosphorus typically diminishes over time under conditions of prolonged high loading rates (such as occur beneath the ponds) due to saturation of the sorption sites on soil minerals. Consequently, results of field studies have been highly variable, ranging from nearly complete removal of phosphorus within a few inches of a field soil surface to high concentrations extending over 2,500 feet from a municipal wastewater percolation pond on Cape Cod (Pitt and others, 1996; Walter and others, 1996; Pettygrove and Asano, 1985). In the case of the Salinas Treatment Facility, the distance from the ponds to the river is only a few hundred feet and loading has been continuous for decades. It is therefore likely that the phosphorus concentration in pond water that reaches the river exceeds the water quality objective.

Thus, seepage into the Salinas River derived from existing Salinas Treatment Facility pond percolation consistently exceeds the water quality objective for nitrate, occasionally degrades Salinas River water quality with respect to TDS and chloride, and probably continually degrades river quality with respect to phosphorus. Because the GWR Project would decrease the annual volume of water percolated at the Salinas Treatment Facility, it would decrease the input of those contaminants to the river and have a beneficial impact on river water quality.

The impact of decreased Salinas Treatment Facility pond percolation on beneficial uses of groundwater in the 180-Foot aquifer depends on the existing groundwater concentration, the concentration in the ponds and the significance threshold for each constituent that affects beneficial use. Those relationships are different for chloride, nitrate, TDS and phosphorus, as explained below.

Groundwater quality impacts would be greatest near the Salinas Treatment Facility, and for this analysis the impact area previously described for water level impacts was also used for water quality impacts: a circle with a 1.5-mile radius surrounding the Salinas Treatment Facility. The Pressure Area water balance in the SVIGSM groundwater model indicates that groundwater recharge from rainfall and irrigation

---

[5] Based on a frequency analysis of daily flows at the Spreckels gage for 1967-2013, there was flow 78 percent of the time.

return flow averages 0.76 ft/yr, which is 38 percent of total groundwater recharge (MWH, 1997). Groundwater recharge from Salinas Treatment Facility percolation averages 0.12 ft/yr when distributed over the circular analysis area. Recharge from Salinas Treatment Facility percolation therefore amounts to approximately 6 percent of total recharge. This means that water quality impacts of changes in Salinas Treatment Facility percolation would be substantially diluted by mixing with other sources of recharge.

Chloride is a relatively conservative solute, which means its concentration does not gradually decrease due to adsorption, degradation or mineral precipitation as it moves through the subsurface. The concentration in the Salinas Treatment Facility ponds is up to three times greater than the existing groundwater concentration, but only 0.9-1.2 times the water quality objective (see Table 4). This means that pond percolation tends to degrade existing groundwater quality and could at most cause groundwater quality to slightly exceed the water quality objective. Therefore, a decrease in Salinas Treatment Facility pond percolation and associated groundwater recharge would probably have a small but beneficial impact on chloride concentration.

Nitrate is usually also a conservative solute in groundwater under typical aerobic conditions. The nitrate concentration in pond water is 2-3 times greater than the existing ambient groundwater concentration and 5-7 times greater than the water quality objective. However, existing nitrate concentrations in the 180-Foot aquifer already exceed the water quality objective by a factor of two. Recharge from pond percolation presently tends to exacerbate an existing degraded condition. Therefore, a decrease in pond percolation would probably have a small but beneficial impact on nitrate concentration.

TDS tends also to be fairly conservative during subsurface transport. The TDS concentration in pond water is 1.5-1.6 times greater than the ambient groundwater concentration. It is greater than the upper secondary MCL for drinking water but less than the Basin Plan water quality objective. Recharge from pond percolation presently tends to degrade groundwater quality with respect to TDS and could impact potable use but does not contribute to an exceedance of water quality objectives. Therefore, a decrease in pond percolation resulting from the GWR Project would tend to improve groundwater quality and maintain beneficial uses.

Finally, the Central Coast Regional Water Quality Control Board has not issued a water quality objective for phosphorus in groundwater. It is not a constituent regulated by drinking water standards or addressed in irrigation water quality guidelines. Therefore, changes in phosphorus concentrations in the 180-Foot aquifer caused by decreased Salinas Treatment Facility pond percolation would not affect beneficial uses.

## Summary of Salinas River Flow Impacts Study

The Monterey Peninsula Water Management District (MPWMD) and the Monterey Regional Water Pollution Control Agency (MRWPCA) are jointly sponsoring the proposed Pure Water Monterey Groundwater Replenishment Project (Proposed Project), a water supply project that will serve northern Monterey County. The project will provide purified water for recharge of the Seaside Groundwater Basin that serves as drinking water supply, and recycled water to augment the existing Castroville Seawater Intrusion Project agricultural irrigation supply. Three of the proposed sources of water supply to be developed for this project are urban runoff from the City of Salinas, agricultural wash water from the Salinas Industrial Wastewater Collection System, and tile drainage and stormwater runoff from the Blanco Drain, all of which currently contribute flow to the Salinas River. The purpose of this study was to (1) analyze the availability of stormwater runoff from the City of Salinas for this project, (2) provide an engineering analysis of the flow reductions in the Salinas River due to diverting City of Salinas stormwater runoff, agricultural wash water and Blanco Drain flows to the Proposed Project, and (3) assess the potential project impacts on hydrology and water quality in the Salinas River.

The southwest portion of the City of Salinas (approximately 2.55 square miles) is tributary to the Salinas River. Runoff from this portion of the City is collected and pumped to the Salinas River, discharging above Davis Road. Average annual runoff to the Salinas River was estimated to be 246 acre-feet per year (AFY). Of this, an average of 225 AFY may be diverted to the Proposed Project using existing capacity in the MRWPCA regional wastewater collection system.

The Salinas Industrial Wastewater Treatment Facility and Collection System serves 25 agricultural processing and related businesses located in the southeast corner of the City. Industrial wastewater is collected and conveyed separately from municipal wastewater, and treated at a facility located along the Salinas River northwest of Davis Road. Treated wastewater is disposed of using evaporation/percolation ponds along the river, with some flows seeping into and contributing to the river. An estimated 3,733 AFY of industrial wastewater may be diverted to the Proposed Project using existing capacity in the MRWPCA regional wastewater collection system. This diversion may reduce inflows to the Salinas River by up to 2,170 AFY[1].

The Blanco Drain is a man-made reclamation ditch draining approximately 6,400 acres of agricultural lands near Salinas, CA. It discharges to the Salinas River at river mile 5, downstream of the Salinas Industrial Wastewater Treatment Facility. Estimated flow in the Blanco Drain is 2,620 AFY. Some or all of this flow may be diverted to the Proposed Project, depending upon the availability of other source waters and the final permitted diversion rate.

[1] Estimate of current percolation to the river prepared by Todd Groundwater, February 2015.

The water quality of the Blanco Drain is poor, and the diversion would require costly facilities, so the use of other sources is preferred.

Flows in the Salinas River below these facilities were estimated using a mass balance model, and a statistical analysis was performed on the results. Diverting agricultural wash water and City of Salinas stormwater to the Proposed Project would reduce average annual flows in the river by less than 1%. If water is also diverted from the Blanco Drain, the average annual flow in the Salinas River decreases by 1.7%. If diversions are made year-round, they will reduce the number of days that minimum flows for fish passage are achieved. Under the current conditions, the target flows for fish passage are met between 24.7% and 27.5% of the time[2], depending upon the target. With the diversions, the target flows are met between 24.1% and 26.5% of the time.

[2] Percentages are calculated as the number of days meeting the minimum passage flow divided by the total number of days modeled. The model covered the river gage period of record, 1932 to 2013.

# Section 1 - Introduction

## 1.1 Project Description

The Monterey Peninsula Water Management District (MPWMD) and the Monterey Regional Water Pollution Control Agency (MRWPCA) are jointly sponsoring the proposed Pure Water Monterey Groundwater Replenishment Project (Proposed Project), a water supply project that will serve northern Monterey County. The project will provide purified water for recharge of the Seaside Groundwater Basin that serves as drinking water supply, and recycled water to augment the existing Castroville Seawater Intrusion Project agricultural irrigation supply.

Source water for the project would include agricultural wash water from the City of Salinas Industrial Wastewater Collection System, stormwater from MRWPCA member cities, secondary-treated effluent from the MRWPCA Regional Treatment Plant, and surface water diverted from the Reclamation Ditch, Tembladero Slough and Blanco Drain. Water supplied to the Proposed Project would undergo primary and secondary treatment at the existing Regional Treatment Plant. The portion used for groundwater recharge would then undergo advanced treatment at a new facility to be located at the MRWPCA site, and then be conveyed to the Seaside Groundwater Basin for injection. The portion used for agricultural irrigation would undergo tertiary treatment at the existing Salinas Valley Reclamation Plant, and distribution through the Castroville Seawater Intrusion Project system.

The MRWPCA provides wastewater treatment for municipalities along the Monterey Bay from Pacific Grove north to Moss Landing, and inland to the City of Salinas. Wastewater is collected in an interceptor pipeline system and conveyed to the Regional Treatment Plant (RTP), located two miles north of the City of Marina. A large portion of this incoming flow is tertiary treated and used for unrestricted agricultural irrigation within the Castroville Seawater Intrusion Project system in the northern Salinas Valley. Flow that is not sent to the tertiary treatment system is discharged through an outfall to Monterey Bay after receiving secondary treatment. The RTP has an average dry weather design capacity of 29.6 million gallons per day (mgd) and a peak wet weather design capacity of 75.6 mgd. It currently receives and treats approximately 17 to 18 mgd of average dry weather flow and therefore has capacity to treat additional flows. The interceptor pipeline system also has currently unused or excess conveyance capacity. Most of the new source waters would be conveyed to the RTP using the existing wastewater collection system; water from Blanco Drain would be conveyed in a new pipeline directly to the RTP.

The purpose of this study is to analyze the availability of urban stormwater runoff from the City of Salinas that currently flows into the Salinas River and to provide an engineering analysis of the potential yields which may be captured and conveyed to the RTP. This study also estimates the Proposed Project's impacts on Salinas River flows, which will include (1) diverting agricultural wash water from the Salinas Industrial Wastewater collection system, (2) capturing stormwater runoff from the City of Salinas, and (3) diverting Blanco Drain flows. The other proposed water sources for the Proposed Project do not affect flow in the Salinas River, and are therefore not included in this analysis. The modeled Salinas River flows from this analysis will be used for the Project's fisheries impacts analysis (by others). Finally, this report provides a summary of the available water quality for the Salinas River and the proposed water sources.

This report builds upon preliminary analysis presented in other reports, including: (1) Technical Memorandum, Salinas Sewage Conveyance Study, prepared by Carollo Engineers; (2) Draft Memorandum, Pure Water Monterey Groundwater Replenishment Project: Impacts of Changes in Percolation at the Salinas Industrial Wastewater Treatment Facility on Groundwater and the Salinas River, prepared by Todd Groundwater; and (3) Revised Draft, Blanco Drain Yield Study, prepared by Schaaf & Wheeler. References are cited as they appear and are listed in Appendix D.

## 1.2 Water Source Descriptions

The City of Salinas is located in the northern part of the Salinas Valley in Monterey County, approximately ten miles east of the Pacific Ocean and adjacent to the Salinas River. Two sources of untreated water for the Proposed Project originate within the City, agricultural wash water and urban stormwater runoff, as discussed below.

### 1.2.1 Salinas Industrial Wastewater Collection and Treatment Systems (Agricultural Wash Water)

The City of Salinas operates an industrial wastewater collection and treatment system that serves approximately 25 agricultural processing and related businesses located in the southeast corner of the City. This water is referred to as agricultural wash water because the majority of it is used to rinse table crops before packaging. This wastewater collection system is separate from the Salinas municipal sewage collection system. Wastewater is conveyed in a network of gravity pipelines to the Salinas Industrial Wastewater Treatment Facility (SIWTF), which is located on the north bank of the Salinas River, downstream of the Davis Road crossing (see Figure A-1). The plant has been in operation since 1944. The SIWTF consists of an influent pump station, an aeration lagoon, percolation ponds, drying beds and rapid infiltration basins to treat, percolate and evaporate the water.

The SIWTF is designed and permitted for an average daily flow of 4.0 million gallons per day (MGD) with a peak flow of 6.8 MGD. The SIWTF operates year-round, with a current peak monthly inflow during summer months of approximately 3.5 to 4.0 mgd. This summer peak corresponds with the peak agricultural harvesting season in the Salinas Valley. In recent years, substantial flows to the SIWTF have continued during the winter months due to the importation of agricultural products from Arizona for processing. Flows in all seasons are expected to increase as additional customers are added to the SIWTF system.

The SIWTF collection system trunk sewer passes through the City's former municipal wastewater treatment plant, known as Treatment Plant No. 1 (TP1), located on Hitchcock Road (see Figure A-2). TP1 is also the location of the MRWPCA Salinas Pump Station, which conveys municipal wastewater to the Regional Treatment Plant via the Salinas Interceptor pipeline. One of the proposed sources of supply for the Proposed Project is agricultural wash water, which may be diverted at TP1 from the industrial collection system to the municipal collection system. The industrial wastewater pipeline is shallower than the municipal wastewater pipeline, so a gravity connection is feasible.

### 1.2.2 Salinas Stormwater

The City of Salinas receives an average of 13.1 inches of rain each year[3]. Four major creeks and several minor tributaries pass through the Salinas area and receive stormwater discharges from the City northeast and adjacent to Highway 101. These creeks are all tributary to the Tembladero Slough and thence to the Old Salinas River channel. Stormwater from the southernmost portion of the City is collected in a storm drain system that flows south toward the Salinas River (Figure A-3). This stormwater system terminates at a lift station on the TP1 property, which discharges to the Salinas River upstream of Davis Road via a 66-inch pipeline (Figure A-4). The pump station has a peak flow capacity of 110 cubic feet per second (cfs). Excess stormwater (peak flows exceeding the pump capacity) overflows to the on-site Blanco Detention Pond. The portion of the City that drains to the Salinas River is approximately 1,631 acres, or 2.55 square miles.

Another of the proposed sources of supply for the Proposed Project is diversion of urban stormwater runoff from the City into the municipal and/or the industrial wastewater collection systems at TP1. The stormwater collection pipelines are shallower than the municipal wastewater pipeline, so a gravity connection to the municipal system is feasible. Connection to the industrial wastewater system would require a gated structure to impound water up to the level of the industrial wastewater collection system pipeline, or a pumped connection may be used. Stormwater flows are highly variable, and occur primarily in the winter months. Peak flows which cannot be captured for the Proposed Project may still be discharged to the Salinas River.

The storm drainage system currently discharges to the Salinas River. During the summer months, the Salinas River flows into the Old Salinas River Channel through a gated culvert on the northern side of the Salinas Lagoon (see Figure A-5 in Appendix A and Figure 1.1, below). Direct discharge to the ocean is blocked by a seasonal sand bar which forms across the mouth of the Salinas Lagoon due to wave and tidal action in the Monterey Bay. The Old Salinas River channel is controlled by tide gates at Potrero Road in Moss Landing. River flow combines with

[3] NWS Gage USW00023233, Salinas Municipal Airport, period 1932-2013

Tembladero Slough flow approximately 1.2 miles above the tide gates. During high winter flows in the Salinas River, the sand bar breaches and the river flows directly to the Bay. When this occurs, the Monterey County Water Resources Agency (MCWRA) closes the slide gate to the Old Salinas River.

**Figure 1.1: Salinas River Lagoon**

Lagoon closed to the ocean (left) and open (right). Arrow indicates gated outlet to Old Salinas River.

The Central Coast Regional Water Quality Control Board (CCRWQCB) has listed the Salinas River below Spreckels on the impaired water body listing pursuant to Section 303(d) of the Clean Water Act for pesticides, nitrate, chloride and other parameters. A summary matrix of 303(d) listed streams is provided as Table B-1. Water quality is discussed in greater detail in Section 3.2 of this report.

### 1.2.3 Blanco Drain

The Blanco Drain is a man-made reclamation ditch draining approximately 6,400 acres of agricultural lands near Salinas, CA. The watershed is between the Salinas River and Alisal Slough, and discharges to the Salinas River at river mile 5 (see Figure A-6). A headwall and flap gate at the lower end of the ditch system prevents seasonal high flows in the Salinas River from migrating up the Blanco Drain channel. Summer flows in the Blanco Drain are generally tile drainage and runoff from irrigated agriculture. Winter flows also include stormwater runoff, but many fields remain in production and are irrigated year-round.

The Central Coast Regional Water Quality Control Board (CCRWQCB) has listed Blanco Drain as an impaired water body pursuant to Section 303(d) of the Clean Water Act for pesticides, nitrate and low dissolved oxygen. Aquatic habitats within the Blanco Drain system are poor. In addition to the poor water quality, the system is generally maintained as a drainage canal without vegetation or tree canopy, and the flap gate prevents fish passage during periods of high flow in the Salinas River.

In 2009-2010, the Monterey County Water Resources Agency's (MCWRA) Salinas River Diversion Facility (SRDF) was constructed downstream of the Blanco Drain. The SRDF includes an inflatable rubber dam that impounds water during the summer months to supply the diversion pump station. To prevent accumulated water in the Blanco Drain channel from submerging the agricultural drains, the Blanco Drain channels were regraded and a new slide gate and pump station were installed at the lower end of the Drain, several hundred feet above the confluence with the Salinas River. The pump station lifts Blanco Drain flows past the slide gate and into the gravity portion of the channel.

The Proposed Project would divert flows from the Blanco Drain at a new pump station, located next to the existing MCWRA pump station, and convey it directly to the RTP via a new pipeline.

# Section 2 - Yield Estimation

## 2.1 Salinas Agricultural Wash Water Capture

Annual yields from the SIWTF were estimated by MRWPCA Staff based upon operational records for the years 2007 through 2013. Total estimated yield of agricultural wash water is 3,733 AFY, based on the projected flows for year 2017 (the year the Proposed Project will commence operation). The Proposed Project is estimated to use 73% to 100% of the available SIWTF influent as source water supply for the Project. Projected monthly inflows to the SIWTF are shown in Table 2-1.

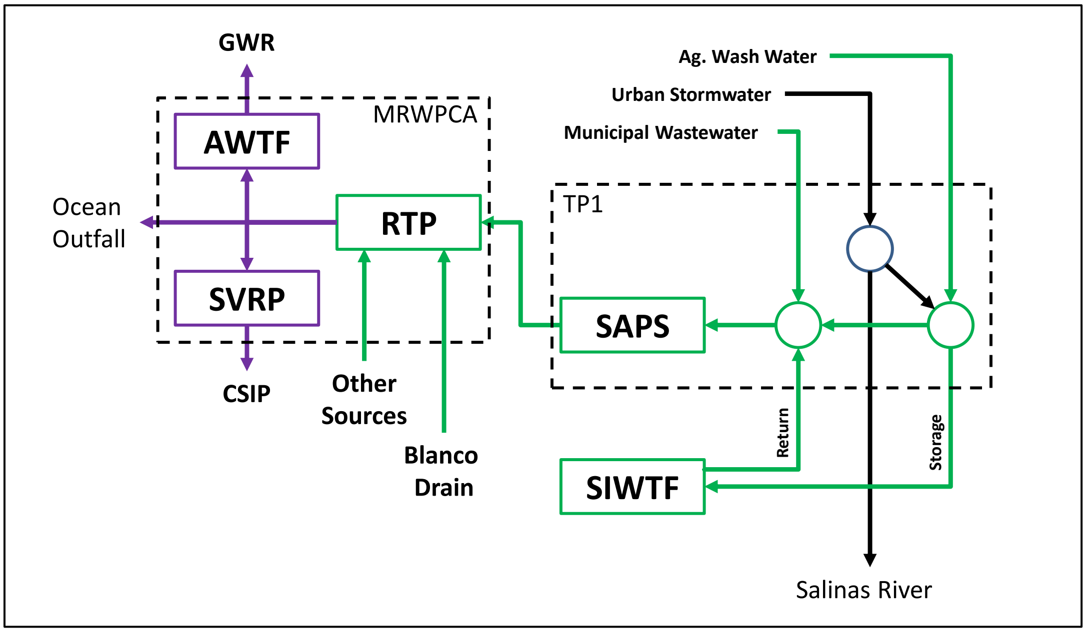
**Table 2-1: Estimated Monthly SIWTF Flows, 2017 Projection[4]**

| Month | Ac-Ft |
|---|---|
| January | 156 |
| February | 158 |
| March | 201 |
| April | 307 |
| May | 311 |
| June | 391 |
| July | 435 |
| August | 444 |
| September | 367 |
| October | 410 |
| November | 329 |
| December | 223 |
| **Total** | **3,733** |

Agricultural wash water would be diverted at the TP1 site into the municipal wastewater collection system. The MRWPCA Salinas Pump Station (SAPS) has a maximum day capacity of 35.4 MGD, but the current peak flow is only 15.6 MGD[5], leaving almost 20 MGD of unused capacity. A valved gravity connection is proposed to transfer agricultural wash water flows into the municipal collection system, retaining the ability to send flows to the existing SIWTF (see Figure 2.1, below, and TP1 piping schematic in Appendix A, Figure A-2). A temporary transfer of agricultural wash water to the municipal wastewater system occurred in the spring and summer of 2014, in response to the prolonged drought conditions. The agricultural wash water was routed backward through the existing municipal-to-industrial emergency overflow pipeline. This increased the amount of secondary-treated effluent available for conversion to recycled water at the Salinas Valley Reclamation Plant.

[4] Projection by Bob Holden, MRWPCA Staff, 2014
[5] MRWPCA Operating Records, 1999-2013

**Figure 2.1: Project Flow Schematic (partial)**



The SIWTF has a design peak flow rate of 6.8 MGD. Water treatment at the SIWTF consists of screening for trash removal, aeration and then percolation/evaporation. Wastewater is treated in a 13-acre aeration lagoon and then discharged by gravity to a series of three percolation/evaporation ponds that have a total surface area of 110 acres[6]. Remaining wastewater is disposed of in 54 shallow drying beds and rapid infiltration beds that are alternately loaded with treated effluent for disposal by percolation and evaporation. Water from the SIWTF percolates into the shallow A-Aquifer above the Salinas Valley Aquitard, which overlies the 180-foot aquifer of the Salinas Groundwater Basin. A large portion of the percolated flow has historically seeped into the Salinas River. Todd Groundwater estimates that in 2013, 20% of the water that was percolated from the SIWTF became recharge to the A-aquifer and 80% seeped to and became surface flow in the Salinas River.

The percolation rate of water in the ponds between 2011 and 2013 declined substantially. The 2013 Annual Report for the SIWTF[7] opines that higher than normal groundwater levels, possibly due to operation of the Salinas River Diversion Facility, may be contributing to this condition. In 2014, the agricultural wash water was diverted to the Regional Treatment Plant between April 1 and October 31 and the water was pumped to the rapid infiltration beds to completely empty the main percolation/evaporation ponds. Prior to this year, the ponds had not been emptied for maintenance of the pond bottoms for more than twelve years (i.e., since emergency repairs were

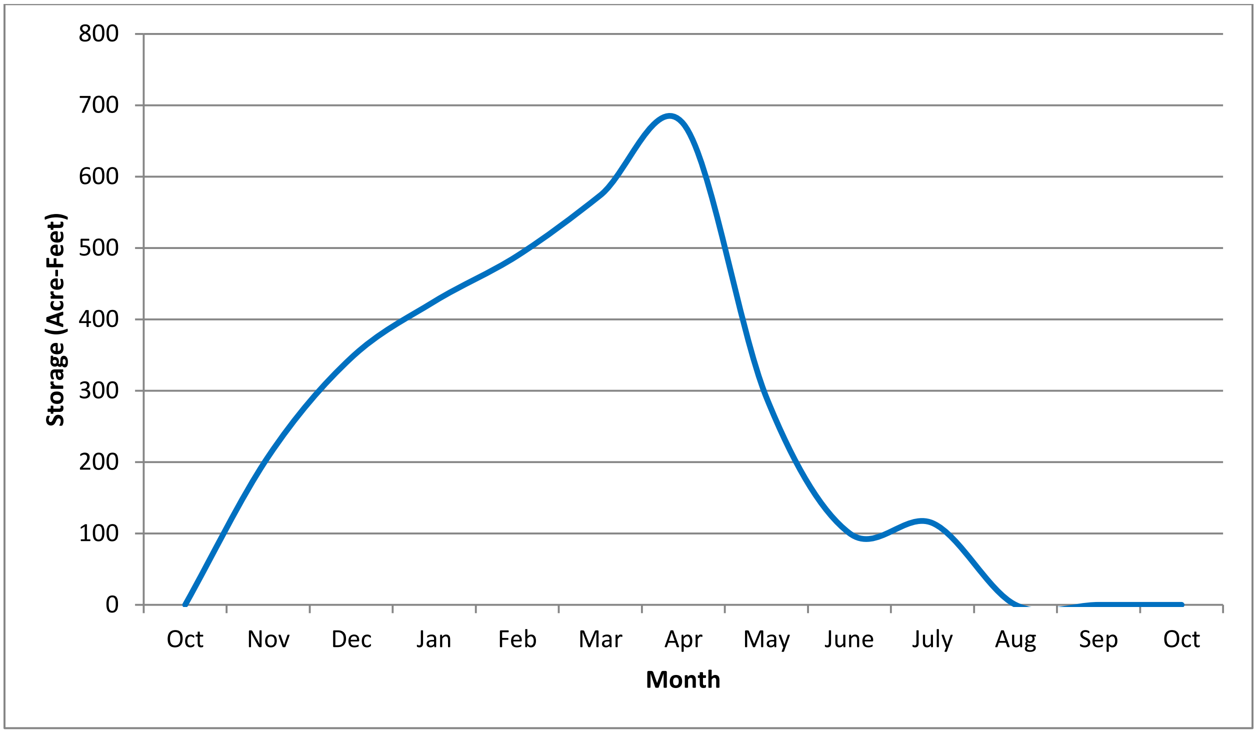
[6] City of Salinas, *Industrial Wastewater Treatment Facility, 2013 Annual Report*, January 2014
[7] City of Salinas, *Industrial Wastewater Treatment Facility, 2013 Annual Report*, January 2014

completed in early 2002). As evidenced by the survey of the empty ponds in 2014, the ponds have accumulated silts (see Figure 2.2).

**Figure 2.2: SIWTF Pond 1 (September 2014)**

The Proposed Project would maximize the use of agricultural wash water by sending flows to the SIWTF ponds from November through April when other sources of water supply are available. From April through October, incoming agricultural wash water would be diverted to the Salinas Pump Station, and stored water from the SIWTF ponds would be pumped back to the Salinas Pump Station. This will allow the production of additional tertiary treated water during the peak irrigation season. The SIWTF ponds can hold approximately 1,250 acre-feet of water. Operating the ponds in this manner, the use of the drying beds and rapid infiltration basins will be eliminated in all but wet years. Assuming the ponds are empty at the start of the filling cycle in November, they will be half full by the end of the filling cycle in April and empty again by mid-August (see Figure 2.3). Increased storage may be achieved by lining one or more ponds to decrease the percolation losses. Stormwater runoff from the City of Salinas that passes through the TP1 site during the filling cycle would also be stored in the SIWTF ponds, if storage capacity exists.

**Figure 2.3: Projected SIWTF Pond Storage (typical year)**[8]



## 2.2 Salinas Stormwater Capture

Estimates of stormwater runoff into the Salinas River from the City of Salinas were made based on daily rainfall gage data, National Resource Conservation Service[9] mapped hydrologic soil group information, and land use as shown on aerial photographs. Calculations were made for each day using the methods in SCS Manual TR-55, Urban Hydrology for Small Watersheds. Runoff curve numbers (CN) were determined based on soil group and cover. Curve numbers appropriate for scrub cover were used for areas of natural vegetation, and curve numbers appropriate for irrigated pasture were used for lawns and other irrigated ground cover. A curve number of 98 for antecedent moisture condition (AMC) II was used for all impervious areas. The runoff curve numbers used to calculate runoff varied between AMC I (with 1.4 inches or less during previous five days) and AMC III (with 2.1 inches or more during the previous five days) depending on the precipitation during the previous five days. Results were aggregated by month and water year (October 1 through September 30).

[8] Storage reflects operational analysis by Larry Hampson, MPWMD, 10/17/2014, with updated percolation rates by Todd Groundwater, 2015.
[9] Formerly the USDA Soil Conservation Service

For each land use and soil group combination, runoff was determined for each day during the period of record. The following equations are used in the NRCS model:

$$R = \frac{(P - 0.2S)^2}{(P + 0.8S)}$$

Where P is the precipitation in inches, R is the runoff in inches, and S is the storage in inches:

$$S = \frac{1000}{CN} - 10$$

Rainfall data for Salinas were obtained from NOAA gage USW00023233, Salinas Airport, Salinas, CA, for the period 10/1/1932 to 12/31/2013. The Salinas Airport Gage has several data gaps (listed below). Data from NOAA gage Salinas #2 (USC00047668) was substituted as indicated below. The average annual precipitation is 13.1 inches/year. Total precipitation by month is shown in Table B-2.

| Date Gap Period | Replaced With |
|---|---|
| 8/6/1941 | None |
| 11/15/1944 – 11/16-1944 | None |
| 6/4/1946 – 7/31/1946 | None |
| 2/1/1948 – 2/29/1948 | None |
| 5/1/1959 – 12/31/1959 | Salinas #2 |
| 7/20/1995 – 7/31/1995 | Salinas #2 |

The portion of the City that drains to the Salinas River is 1,631 acres, or approximately 2.55 square miles (see Figure A-3). The land use and soil types are shown in Table 2-2. Using the method described above, the total estimated runoff into the Salinas River from the City averages 246 acre-feet per year (see Appendix B, Table B-3).

**Table 2-2: Land Use, Areas and Curve Numbers**

| Land Use | Soil Group | Curve Number | Total Area | Percent Impervious | Impervious Area | Pervious Area |
|---|---|---|---|---|---|---|
| | | (AMC II) | (acres) | | (acres) | (acres) |
| Single Family Residential | C | 83 | 1,108 | 40% | 443.4 | 665.0 |
| Commercial | C | 94 | 51 | 90% | 46.0 | 5.1 |
| Open Space | C | 79 | 184 | 10% | 18.4 | 165.9 |
| Single Family Residential | D | 87 | 261 | 40% | 104.5 | 156.8 |
| Commercial | D | 95 | 16 | 90% | 14.2 | 1.6 |
| Open Space | D | 84 | 10 | 10% | 1.0 | 9.4 |
| **Totals** | | | **1,631** | | **628** | **1,004** |
| Net Impervious Area | | 98 | | | **628** | |

Stormwater from the City of Salinas flows to the City's Salinas River Pump Station, located adjacent to the TP1 site and the MRWPCA Salinas Pump Station (Figure A-2). The site elevation at TP1 is approximately 36-ft. The gravity stormwater mains enter the Salinas River Pump Station at invert elevation 23-ft (+/-)[10], or about 13-ft below ground surface. The sanitary sewer mains entering the MRWPCA pump station have an invert elevation of 16-ft (+/-), or about 20-ft below ground surface. The sanitary sewer main is deeper, therefore it is possible to connect the stormwater system to the sanitary system using a gravity pipeline and check valve.

The MRWPCA operates three wastewater interceptor systems that convey flows to the Regional Treatment Plant: the Moss Landing-Castroville Interceptor from the north, the Monterey-Seaside-Fort Ord-Marina Interceptor from the south, and the Salinas Interceptor from the east (Figure A-7). As discussed above, the MRWPCA Salinas Pump Station has a maximum day capacity of 35.4 MGD, a current peak flow of 15.6 MGD[11], and approximately 20 MGD of unused capacity. Runoff capture from Salinas was calculated based on an upper diversion limit of 61 acre-feet/day (= 20 MGD). No lower limit was needed because this system may be configured to capture all stormwater below the daily limit. If the combined stormwater and agricultural wash water flows exceed 20 MGD, the excess stormwater would bypass to the existing Salinas River Pump Station, or may be routed to the SIWTF for storage using the existing Industrial Wastewater collection system. The estimated average annual runoff capture was 225 AFY (see Tables B-4 and B-5 for monthly model results). The estimated runoff capture varied based on the annual rainfall pattern, from a minimum of 19 AFY to a maximum of 654 AFY.

### 2.3 Blanco Drain Flow Capture

Annual yields from the Blanco Drain were estimated by Schaaf & Wheeler[12] based on operational records for the existing Blanco Drain pump station. Monthly pump station flows, rainfall data and Castroville Seawater Intrusion Project delivery records were used to determine the relationship between Blanco Drain flows and rainfall and applied irrigation across the 6,000 acre drainage basin. An average 17% of the total precipitation and applied irrigation returns as flow in the Blanco Drain. The estimated average monthly flows in the Blanco Drain are shown in Table 2-3. A full discussion of the estimating methodology and the underlying data are available in the Blanco Drain Yield Study report.

[10] Using the City of Salinas IWTF Ponds for Stormwater Storage, Kimley-Horn and Associates, 2013

[11] MRWPCA Operating Records, 1999-2013

[12] Revised Draft Blanco Drain Yield Study, Schaaf & Wheeler, 2014

**Table 2-3: Estimated Monthly Flows in Blanco Drain**

| Month | Applied Irrig + Precip | 17% return | Avg Return Flow Rate |
|---|---|---|---|
| | AF | AF | CFS |
| January | 1,229 | 209 | 3.4 |
| February | 1,314 | 223 | 4.0 |
| March | 1,446 | 246 | 4.0 |
| April | 1,481 | 252 | 4.2 |
| May | 1,323 | 225 | 3.7 |
| June | 1,613 | 274 | 4.6 |
| July | 1,629 | 277 | 4.5 |
| August | 1,436 | 244 | 4.0 |
| September | 1,080 | 184 | 3.1 |
| October | 989 | 168 | 2.7 |
| November | 782 | 133 | 2.2 |
| December | 1,088 | 185 | 3.0 |
| **Totals** | **15,410** | **2,620** | |

Flow capture from the Blanco Drain was estimated based on two diversion rates. The permitting process for a water right diversion under 3 cfs is shorter than for a larger water right, so the Proposed Project assumes an initial water right diversion at 2.99 cfs, and an ultimate water right allowing diversions at up to 6 cfs. Because the water quality and in-stream habitat in the Blanco Drain is poor, it was assumed that all of the available flows may be diverted (that is, no minimum flow into the Salinas River would be required). The estimated monthly diversions are shown in Table 2-4, below. The Proposed Project would develop multiple sources of water supply. Water from the Blanco Drain is only projected for use between March and September, although diversions in other months may occur depending upon the availability of supply from other sources. For this analysis, year-round diversions under the proposed water rights were considered.

**Table 2-4: Estimated Monthly Diversions from Blanco Drain**

| Month | Diverting at 2.99 cfs | Diverting at 6.0 cfs |
|---|---|---|
| | AF | AF |
| January | 184 | 209 |
| February | 166 | 223 |
| March | 184 | 246 |

| May | 184 | 225 |
| June | 178 | 274 |
| July | 184 | 277 |
| August | 184 | 244 |
| September | 178 | 184 |
| October | 168 | 168 |
| November | 133 | 133 |
| December | 184 | 185 |
| **Totals** | **2,104** | **2,620** |

## 2.4 Salinas River Flows

The Salinas River is the largest river of the Central Coast of California, running 170 miles and draining 4,160 square miles (Figure A-8). It originates near the town of Santa Margarita in San Luis Obispo County and flows north-northwest through Monterey County and into the Monterey Bay. The Salinas River watershed is bounded by the Gabilan Range to the east and the Sierra de Salinas and Santa Lucia Range on the west. The combination of steep terrain on the sides of the watershed and intense farming of the valley floor leads to high sediment loads within the river. The Salinas River has three main tributaries, the Nacimiento, San Antonio and Arroyo Seco Rivers. Historically, the River was dry during summer months and prone to flooding during extreme winter and spring storm events. Levees were constructed to prevent flooding and restrict channel migration on the historic floodplain and adjacent lands[13]. Modifications to the natural hydrologic condition occurred with the construction of reservoirs for flood control and water supply.

**Table 2-5: Reservoirs in the Salinas Basin**

| Reservoir Name | Storage Capacity<br>Drainage Area | Constructed | Owner |
|---|---|---|---|
| Lake Nacimiento | 377,900 ac-ft<br>362 sq-mi | 1957 | Monterey County Water Resources Agency |
| Lake San Antonio | 335,000 ac-ft<br>344 sq-mi | 1967 | Monterey County Water Resources Agency |
| Santa Margarita Lake | 23,843 ac-ft<br>112 sq-mi | 1941 | City of San Luis Obispo |

The Salinas Valley Groundwater Basin extends along the river valley floor from Bradley north to the Monterey Bay. It provides approximately 500,000 acre-feet per year of water supply for municipal, industrial and agricultural use. The groundwater basin has four designated subareas, the Upper Valley, Forebay, East Side and Pressure (Figure A-9). The groundwater basin is recharged in all but the Pressure Subarea, which has a clay layer above the major water bearing layers[14]. Monterey County Water Resources Agency (MCWRA) releases flows from Lakes Nacimiento and San Antonio through the spring and summer months to recharge the groundwater basin. Santa Margarita Lake is used for municipal water supply in San Luis Obispo County and is not released to the river. In 2009, the MCWRA constructed the Salinas River Diversion Facility (SRDF) near the Salinas Valley Reclamation Plant (Figure A-10). Water released from San Antonio and Nacimiento Reservoirs which has not percolated into the Salinas Valley Groundwater Basin may be rediverted at the SRDF. The facility includes an inflatable

[13] Salinas River Stream Maintenance Program EIR, Executive Summary, Cardno ENTRIX, 2013
[14] DWR Bulletin 118, description of Subbasin 3-4.01

rubber dam that creates a seasonal intake pool for the diversion pump station, a metered release weir for maintenance of downstream flows and a fish ladder (Figure 2.4).

**Figure 2.4: Salinas River Diversion Facility[15]**

The U.S. Geologic Survey operates a stream flow gage on the Salinas River below Spreckels, approximately 3-miles upstream of Davis Road and the SIWTF. Daily flow readings are available from October 1, 1929 to present. Data were analyzed for the period 10/1/1931-12/31/2013, to be consistent with the period of precipitation data used for runoff analysis. The stream gage data allow a review of the river conditions before the construction of the two major reservoirs (1932-1956), regulated flows for groundwater recharge (1957-2009) and increased flows for rediversion at the SRDF (2010-2013) (see Table 2-6, below, and Tables B-6, B-7 and B-8 in Appendix B). The decline in average annual flows during the regulated period was approximately 90,000 AFY, due to a combination of increased groundwater recharge, increased evaporative losses (from the reservoirs), lower average rainfall than the previous period and likely increases in riparian water use due to year-round availability. Summer flows (July-September) averaged less than 5 cfs under natural conditions, but increased to over 20 cfs once the reservoirs were operated to maintain year-round flow in the river. Similarly, average winter flows (January-March) decreased by 25% due to the capture of peak flows in the reservoirs.

[15] AMBAG aerial imagery

**Table 2-6: Annual Flow, Salinas River near Spreckels**

| Water Years (Oct to Sep) | Average Flow (AFY) | Median Flow (AFY) | Period Description |
|---|---|---|---|
| 1932-2013 | 297,070 | 121,392 | All years of record |
| 1932-1956 | 362,407 | 224,798 | Prior to reservoirs |
| 1957-2009 | 276,431 | 88,450 | Regulated Flows |
| 2010-2013 | 162,187 | 112,900 | Increased releases for SRDF |

As a condition of operating the SRDF, MCWRA must maintain certain in-stream flows in the Salinas River. When San Antonio and Nacimiento Reservoirs have a combined storage of 220,000 acre-feet, the SRDF has a requirement to release (1) a minimum of 15 cfs downstream from April 1 to June 30, and (2) a minimum of 2 cfs downstream from July 1 to the end of the SRDF operating season for maintenance of the Salinas River Lagoon habitat. Higher flow releases are triggered during steelhead migration season if the Salinas Lagoon is open to the ocean. When the combined storage in the two reservoirs is under 220,000 ac-ft and/or the water year type is Dry, the minimum bypass requirement for Salinas River Lagoon habitat maintenance is 2 cfs while the SRDF is in operation. In Table 2-7, the recorded daily by-passed flows at the SRDF during years 2012 and 2013 are provided (fish ladder plus regulating weir, as shown in Figure 2.5). Unmetered flows also occurred across the 144-ft wide dam face. The table includes the number of days the average water level behind the dam was higher than the dam crest. Water year 2012 was classified as a dry year, so the trigger for fish passage releases was not met. Water year 2013 was classified as a dry-normal year, so increased releases for Salinas Lagoon habitat maintenance were made. The required minimum releases are included in the table.

The proposed project will reduce inflows above the SRDF by capturing flows from the Blanco Drain and reducing percolation from the SIWTF into the river. Those reductions are tabulated by month in Table 2-8. Urban stormwater will also be captured, but rain events are typically single-day occurrences, so they were omitted from the table. The project will reduce inflows by 3 cfs up to 8.6 cfs during the SRDF operating season. In a dry year, this should not affect the achievement of minimum releases, but it will reduce the frequency of unmetered releases over the dam crest. During years where passage flow releases are required, full diversion under the proposed project will reduce the frequency of unmetered releases over the dam crest, and may affect the achievement of minimum releases. The MCWRA releases between 350 cfs and 550 cfs from Nacimiento and San Antonio Reservoirs when the SRDF is operating, but less than 50 cfs (about 10%) remains in-stream at the Spreckels gage[16]. The majority of the released flow goes to groundwater recharge and riparian evapotranspiration above Spreckels. The SRDF diversion rate is an average 20 cfs. Due to the significant losses and travel time between the

[16] Salinas Valley Water Project, Annual Flow Monitoring Report, Water Year 2013, and USGS Gage 11152500, Salinas River near Spreckels

reservoirs and the SRDF, flows reductions affecting the by-pass releases would likely be addressed by temporarily reducing SRDF pumping before adjusting the reservoir release schedule. A portion of the diversions made for the proposed project will be used to augment the CSIP supply, off-setting the effect of any temporary SRDF reduction.

The SRDF was not operated during 2014 due to the extended drought. Minimum fish releases were made from San Antonio and Nacimiento Reservoirs, but no additional conservation releases. Measurable flow at the Spreckels gage was recorded only on December 11-12 of that year. Agricultural wash water was diverted from the SIWTF to the municipal wastewater system starting in April 2014 to provide additional source water to the Salinas Valley Reclamation Plant, and by late July the SIWTF ponds had been drained for maintenance. The mean water level for the Salinas River Lagoon[17] was 10.42 feet in August 2013 and 10.50 feet in August 2014. The water level in the lagoon is controlled by a slide gate to maintain habitat, so the effect of diverting agricultural wash water could not be observed.

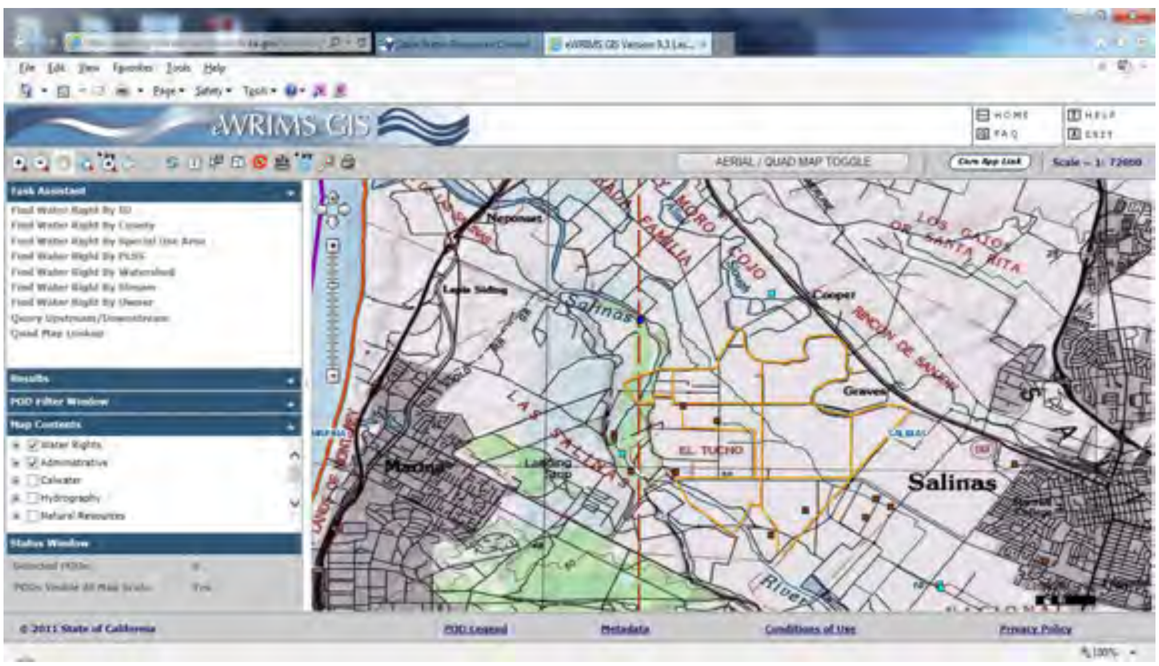
[19] Salinas Valley Water Project, Annual Flow Monitoring Report, Water Year 2012 and 2013

## 2.5 Water Rights Database Review

Water that enters surface streams and rivers is considered water of the state. A water rights permit is required to impound or divert waters of the state, except for certain riparian uses. Stormwater runoff from the City of Salinas does not become water of the state until it is discharged to the river. Agricultural wash water originates as groundwater supply, and does not become water of the state until it percolates into the river. Stormwater and agricultural return flows in the Blanco Drain would be subject to water rights permitting rules. Existing surface water rights were researched to assess potential impacts to current water right holders or challenges to the proposed diversions.

The State Water Resources Control Board Electronic Water Rights Information Management System (eWRIMS) was queried to identify existing water rights in the Lower Salinas Watershed. A listing of all current water rights for Monterey County was obtained using a database query. The Points of Diversion (PODs) within the Lower Salinas watershed and vicinity were identified using the on-line GIS mapping tool. The POD listing was used to create a tailored list of water rights within the area of interest (see Tables B-9 and B-10).

**Figure 2.6: SWRCB eWRIMS Interface**



The SWRCB Water Rights Order 98-08, Declaration of Fully Appropriated Stream Systems in California, identifies those stream segments which cannot support additional authorizations for diversion. The Lower Salinas River was not listed in that decision, so there is no regulatory prohibition on requesting a water right on the river or its tributary streams.

The water rights listing includes several water right types:

- Appropriative, for the diversion and use of surface water.
- Stockpond, for the on-stream impoundment and use of water.
- Statements of Diversion and Use, for reporting riparian use of surface water and for the use of groundwater. Statements of Diversion and Use are also used for claims of pre-1914 appropriative water rights. The limitation of the eWRIMS database is that most Claimed water rights do not appear with a Face Amount the way Appropriative Rights are listed.

The majority of the existing points of diversion downstream of Davis Road are for groundwater use. The sources for these are variously listed as "Salinas River Underflow", "Salinas Valley Basin" and "Groundwater Use." The shallow "A-Aquifer" groundwater in this area is not used due to poor water quality. Wells in this area tap the 180-ft and 400-ft aquifers of the Salinas Valley Groundwater Basin (SVGB), which are recharged from the Forebay and Upper Valley subareas and are separated from the overlying A-Aquifer by the Salinas Valley Aquitard[20]. Reducing surface water discharges to the river for this project should not affect groundwater yields from the SVGB.

The MCWRA has three water rights (Permits 10137, 21089 and 12261) for water diversion and storage in San Antonio and Nacimiento Reservoirs, with authorized points of rediversion at the Salinas River Diversion Facility (SRDF) (small blue square on the map above). The MCWRA must release flows from the upstream reservoirs in order to redivert them at the SRDF. There are no other surface water rights with points of diversion below the SRDF. MCWRA has a fourth water right, Permit 11043, for run-of-river flows with two authorized points of diversion upstream of Davis Road (one near Spreckels and one near Soledad). This fourth water right has not been used but has a priority date of July 11, 1949.

# Section 3 - Impacts Analysis

## 3.1 In-Stream Flow Analysis

A quantitative analysis of the Project's effects on the Salinas River was performed by modeling the daily river flows under the current condition and under several project conditions. The change in river flows can then analyzed for effects on (1) downstream water rights diversions, and (2) in-stream habitat. There are no run-of-river water rights downstream of the Proposed Project's source water diversions; therefore the assessment of river flow changes only looks at flow levels required to maintain habitat. In the Steelhead Habitat and Passage Effects Assessment Technical Memorandum, the fisheries biologist identified the South-Central California Steelhead as a Federally Threatened species with Critical Habitat occurring in the Salinas River. The biologist further identified four target flow rates for the Salinas River, as required for juvenile and smolt migration downstream and adult migration upstream (Table 3-1).

**Table 3-1: Target Flows for Maintenance of Steelhead Critical Habitat[21]**

| Case | Required Flow Depth | Channel Width | Target Flow |
|---|---|---|---|
| Adult Immigration | 0.6 feet | 25% of channel | 72 cfs |
| Adult immigration | 0.6 feet | 8 feet (min) | 60 cfs |
| Juvenile and Smolt Emigration | 0.4 feet | 25% of channel | 56 cfs |
| Juvenile and Smolt Emigration | 0.4 feet | 8 feet (min) | 50 cfs |

The three proposed sources of supply for the Proposed Project contribute flow to the Salinas River above the SRDF. Impacts on river flows due to removing or reducing these sources were assessed using a mass-balance analysis at a point below the SRDF rubber dam (see Figure 3.1, below). Table 3-2 provides the relative locations of the facilities shown in Figure 3.1.

**Table 3-2: Relative Locations of Facilities in this Analysis**

| Description | River Mile (Salinas River) |
|---|---|
| USGS Gage 11152500, Spreckels | 13.2 |
| Salinas Stormwater Outfall | 11.2 |
| Davis Road | 10.9 |
| SIWTF Ponds | 9.2 – 10.7 |
| Blanco Road | 7.5 |
| Blanco Drain | 5.1 |
| SRDF | 4.8 |
| Analysis Point | 4.7 |

[21] Pure Water Monterey Groundwater Replenishment Project, Steelhead Habitat and Passage Effects Assessment Technical Memorandum, HDR Engineering, 2015

Flows in the Salinas River were calculated using a daily time step model and aggregated on a monthly basis, using the following equations:

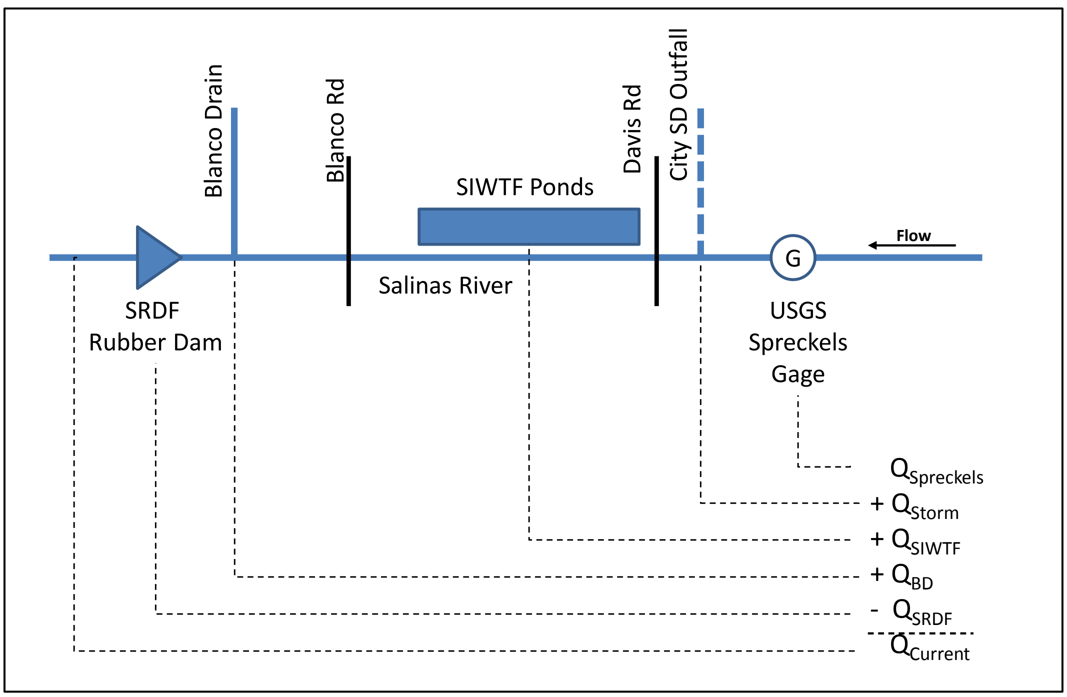
Current Condition: $Q_{Current} = Q_{Spreckels} + Q_{Storm} + Q_{SIWTF} + Q_{BD} - Q_{SRDF}$

Project Condition: $Q_{Project} = Q_{Current} - Q_{StormCapture} - Q_{SIWTF} - Q_{BD\_Capture}$

Where:

| | |
|---|---|
| $Q_{Current}$ | is the estimated river flow below the Salinas River Diversion Facility (SRDF) |
| $Q_{Spreckels}$ | is the USGS gaged flow in the Salinas River at Spreckels |
| $Q_{Storm}$ | is the stormwater discharge from Salinas (estimated by S&W) |
| $Q_{SIWTF}$ | is the seepage from the SIWTF ponds to the Salinas River (estimate by Todd) |
| $Q_{BD}$ | is the Blanco Drain discharge to the Salinas River (estimated by S&W) |
| $Q_{SRDF}$ | is the recorded diversions at the SRDF (2010-2013 only) |
| $Q_{StormCapture}$ | is the estimated stormwater capture at TP1 |
| $Q_{BD\_Capture}$ | is the estimated diversion from the Blanco Drain |
| $Q_{Project}$ | is the estimated river flow below the SRDF under project conditions |

**Figure 3.1: Salinas River In-Flow and Out-Flow Schematic**



Monthly water balances for the various percolation facilities at the SIWTF were estimated for baseline and GWR Project conditions by Todd Groundwater (2015). The calculations accounted for rainfall, evaporation and percolation at the aeration pond, Ponds 1, 2 and 3, the drying beds and the rapid infiltration basins. Measurements of river flow and quality in fall 2013 indicated that about 3.0 cfs of pond percolation was flowing via subsurface flow paths into the river. Under GWR Project operation, Ponds 1, 2 and 3 would be mostly full in winter and spring and be dry in summer and fall. The change in monthly seepage into the river would therefore probably range from 0 to 3 cfs. The impact analysis here assumes a worst-case change of 3.0 cfs year-round, which would require lining the ponds to prevent percolation or diverting flows to the RTP year-round.

Daily calculations were performed for the period 10/1/1931 to 12/31/2013 for four conditions:

Case 0: Current condition (no diversions)

Case 1: Divert Ag. Wash Water and Stormwater at TP1, no diversion at Blanco Drain

Case 2: Divert Ag. Wash Water and Stormwater at TP1, and 2.99 cfs at Blanco Drain

Case 3: Divert Ag. Wash Water and Stormwater at TP1, and 6.0 cfs at Blanco Drain

This methodology does not consider other inflows (agricultural tile drainage and seepage from other wastewater treatment facilities) and losses (evaporation and seepage into the shallow aquifer) between the Spreckels gage and the SRDF. However, these other inflows and losses are not affected by the proposed project, so their omission does not affect the comparison of the current condition model to the project condition models.

The modeled average annual flow totals are provided in Table 3-3, below. As can be seen, the proposed diversions account for less than 2% of the average annual flow downstream of the SRDF. Assuming that pond percolation would continue for more than six months per year, the reduction in average annual flow downstream of the SRDF would be less than 1%.

**Table 3-3: Modeled Average Annual Flows**

| Case | Reduction | Net Flow below SRDF | Percent of Case 0 |
|---|---|---|---|
| | (AFY) | (AFY) | |
| 0, Base Condition | | 301,916 | |
| 1, Divert at TP1 only | 2,397 | 299,519 | 99.21% |
| 2, Divert at TP1 plus 2.99 cfs at Blanco Drain | 4,501 | 297,415 | 98.51% |
| 3, Divert at TP1 plus 6.0 cfs at Blanco Drain | 5,017 | 296,899 | 98.34% |

Seepage flows converted using 1 cfs = 724 AFY
Modeled period is 10/1/1931 to 12/31/2013

A comparison of the total number of days meeting the four flow targets is presented in Table 3-4. The detailed modeling results are presented in Appendix C as (1) statistical counts of days per month that the modeled flow equaled or exceeded the target flow, under the four conditions listed above, (2) monthly percentile tables of the modeled flow rates under the four conditions, and (3) graphs of the monthly flow exceedance curves. An assessment of the impacts on fish passage was prepared separately, based upon the monthly results.

**Table 3-4: Model Results, Number of Days meeting Flow Targets**

| Flow | Case 0 | | Case 1 | | Case 2 | | Case 3 | |
|---|---|---|---|---|---|---|---|---|
| (cfs) | No. Days | Percent | No. Days | Percent | No. Days | Percent | No. Days | Percent |
| 72 | 7,428 | 24.72% | 7,325 | 24.38% | 7,242 | 24.11% | 7,239 | 24.10% |
| 60 | 7,814 | 26.01% | 7,701 | 25.63% | 7,604 | 25.31% | 7,596 | 25.28% |
| 56 | 7,984 | 26.58% | 7,841 | 26.10% | 7,755 | 25.81% | 7,743 | 25.77% |
| 50 | 8,252 | 27.47% | 8,083 | 26.90% | 7,971 | 26.53% | 7,960 | 26.50% |

Percentage calculated out of 30,043 total days modeled.

When the Salinas River Lagoon is closed to the ocean, the water level is maintained at 3-feet above mean sea level by use of a slide gate controlling outflow into the Old Salinas River channel. This management method creates a backwater effect that extends 3 to 4 miles upstream, nearly reaching to the SRDF site[22]. Reducing the excess flows passing the SRDF during the summer months may reduce the upstream extent of the backwater effect, exposing more of the seasonal sand bars in the channel bottom. The minimum by-pass flows under the SRDF and agricultural return flows along this reach of the river will prevent the channel from completely dewatering.

The outflow from the Salinas River Lagoon into the Old Salinas River Channel through the slide gate is limited to 120 cfs[23]. During the winter-spring wet season, peak flows due to rain events breach the coastal dune and open the lagoon to the ocean. Once the lagoon is open to the ocean, the slide gate to the Old Salinas River is closed. Capturing urban stormwater during lagoon opening rain events may delay the opening by a few hours, because the urban runoff from Salinas reaches the Salinas River earlier than runoff from other portions of the watershed. If the season is wet enough to maintain the open mouth of the lagoon into the spring irrigation season, the Project will not need to divert flows from the Blanco Drain, so urban runoff capture would be the only project diversion affecting river flows.

[22] Historic imagery and topographic maps

[23] Coastal Commission Permit No. 3-95-58

### 3.2 Water Quality Considerations

The Central Coast Regional Water Quality Control Board (CCRWQCB) Water Quality Control Plan for the Central Coast Basin (Basin Plan) designates beneficial uses of the Salinas River below Spreckels as including municipal and domestic supply, agricultural supply, non-contact water recreation, wildlife habitat, warm and cold water fish habitat, freshwater replenishment (of the Salinas Lagoon) and commercial or sport fishing.

The Salinas River is listed as an impaired water body pursuant to Section 303(d) of the Clean Water Act for chlorides, pesticides, Escherichia coli, fecal coliform, nitrate, total dissolved solids, turbidity and other factors. Water quality has been sampled and monitored for the past 15 years under various programs, including the Central Coast Ambient Monitoring Program (CCAMP) under the RWQCB, the Central Coast Watershed Studies (CCoWS) program of the Watershed Institute at California State University Monterey Bay, and the Cooperative Monitoring Program under the Conditional Waiver of Waste Discharges from Irrigated Lands (Ag Waiver). The results of these programs have been consolidated in Table B-11, Stream Water Quality, for the Salinas River, Salinas Lagoon and the Old Salinas River. Figure A-8 shows the primary sampling locations.

The Central Coast RWQCB adopted order R3-2013-0008 to establish Total Maximum Daily Loads (TMDL) for pollutants in the lower Salinas River Basin in 2013. These and other applicable water quality standards are consolidated in Table B-12, Total Maximum Daily Loads. A summary of the key parameters for the Salinas River are shown in Table 3-5, below.

**Table 3-5: Water Quality Parameters, Salinas River below Spreckels**

| Parameter | Units | Mean[1] | Max[1] | Standard[2] |
|---|---|---|---|---|
| Ammonia as N, Unionized | mg/L | 0.02 | 0.13 | 0.025 |
| Ammonia as NH3 | mg/L | 0.12 | 0.98 | 0.025 Note 3 |
| Chlorophyll a, water column | mg/L | 0.0033 | 0.023 | 0.015 |
| Chlorpyrifos | mg/L | 0.0011 | 0.029 | 0.00025 |
| Diazinon | mg/L | 0.008 | 0.22 | 0.00016 |
| Dissolved Solids, Total | mg/L | 369.60 | 610.00 | 1000 Note 3 |
| Nitrate as N | mg/L | 5.08 | 78.00 | 1.4 (May-Oct)<br>8.0 (Nov-Apr) |
| OrthoPhosphate as P | mg/L | 0.23 | 2.60 | 0.07 (May-Oct)<br>0.3 (Nov-Apr) |
| Oxygen, Dissolved | mg/L | 0.36 | 2.66 | > 7.0 |
| Turbidity | NTU | 118.66 | 2,584.00 | 10 Note 3 |

1. Max and Mean values reflect all results in the CCAMP/CCoWS database
2. Listed Total Maximum Daily Load (TMDL) established by CC RWQCB, except where noted
3. Proposed TMDL from CCAMP program

The City of Salinas operates the SIWTF under Waste Discharge Requirement Order R3-2003-0008. The City also has an NPDES permit (number CA0049981, order R3-2012-0005) for municipal stormwater discharges. Both of these permits require water quality monitoring and reporting. For the SIWTF, influent and effluent water quality is monitored at the plant. For stormwater, the City monitors stormwater outfalls and receiving streams at various locations (see Figures A-11 and A-12). Table 3-6, below, shows the most recent sampling results for those parameters included in Table 3-5.

**Table 3-6: City of Salinas, Water Quality Sampling**

| Analyte Name | Units | Stormwater at 309U19 | SIWTF Effluent[1] | Standard |
|---|---|---|---|---|
| Ammonia as N, Unionized | mg/L | 0.00022 | NR | 0.025 |
| Chloride | Mg/L | NR | 318 | 150 |
| Dissolved Solids, Total | mg/L | 50.8 | 1011 | 1000 |
| Nitrate as N | mg/L | ND | 0.12 | 1.4 (May-Oct)<br>8.0 (Nov-Apr) |
| OrthoPhosphate as P | mg/L | 0.2 | NR | 0.07 (May-Oct)<br>0.3 (Nov-Apr) |
| Oxygen, Dissolved | mg/L | 5.54 | >4.5 | >7 |
| Turbidity | NTU | 44.7 | NR | 10 |

Stormwater results from 2012-2013 season, SIWTF results from 2013
ND = not detected, NR = testing not required
Note 1: Effluent sampling conducted on flows from ponds to disposal beds

The results above are typical of those in previous annual reports. The stormwater runoff is generally of equal or better quality than the Salinas River that receives it. It meets the Central Coast RWQCB Basin Plan objectives in some categories. In the categories of turbidity and orthophosphate, it exceeds the basin plan objectives but is below the average concentration in the receiving stream. Although the stormwater runoff may slightly improve the quality of the water in the river, the Salinas River basin is so large that diverting urban stormwater runoff to the Proposed Project should have no appreciable effect on water quality within the Salinas River.

Effluent from the SIWTF is not tested for ammonia or orthophosphate, so a general water quality comparison with the Salinas River cannot be made. The effluent exceeds the Basin Plan objective for Chloride and Total Dissolved Solids (TDS). Diverting Industrial Wastewater to the Proposed Project may result in reduced TDS levels in the river, particularly in summer months when percolation from the SIWTF makes up a significant portion of the river flow. Under natural conditions, the impact of removing inflows to downstream riparian habitats during the summer months may have a greater impact than the benefit of reducing the TDS might justify. However, under the current condition with increased flows released to the SRDF during the summer months, the SIWTF inflows represent a smaller percentage of the total streamflow and the impact of their removal would be reduced.

### 3.3 Hydrology Considerations

The California Environmental Quality Act (CEQA) requires that effects of the Proposed Project on surface water hydrology be analyzed to identify impacts in the following areas:

a. Would the project substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, in a manner that would result in substantial erosion or siltation on- or off-site?

The Project components addressed in this report, diversions of agricultural wash water, Salinas urban runoff and flows from the Blanco Drain, would capture some stormwater which currently flows to the Salinas River. Reducing urban runoff into the Salinas River, particularly the first flush as storms begin, would reduce the amount of suspended solids conveyed to the river and may reduce peak flows being discharged into the river. The change in operation at the SIWTF to facilitate the diversion of agricultural wash water would have no effect on erosion and siltation, because that water is currently disposed of using evaporation and percolation. The diversion of Blanco Drain flows would reduce the amount of sediment carried from the Blanco Drain into the main stem of the Salinas River, and the channel around the inlet structure for the diversion pump station would be lined with concrete to prevent local scour and erosion. The Blanco Drain diversion may not be required to operate during wet winter months when storm runoff typically occurs. In that case, the conveyance of sediment from the Blanco Drain into the River will be no greater than under the current condition.

The construction of the Blanco Drain diversion structure and pipeline will require open-cut excavation, which will require the use of erosion and sediment controls to prevent the migration of sediments into the river. The pipeline crossing of the river will be installed using trenchless methods to avoid impacts to the channel. The pipeline trench will be restored to prevent erosion, either by reseeding (if outside a roadway) or by resurfacing if in a trafficked area.

b. Would the project substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or substantially increase the rate or amount of surface runoff in a manner that would result in flooding on- or off-site?

The Project would not make physical changes to the Salinas River, and the operation of the Project would reduce the amount of surface runoff entering the river. The proposed project components would increase impervious areas by a small amount including less than 1000 square feet each at the TP1site, the SIWTF and the Blanco Drain. The Project would not substantially alter the existing drainage patterns of any of the proposed project sites.

c. Would the project create or contribute runoff water which would exceed the capacity of existing or planned stormwater drainage systems or provide substantial additional sources of polluted runoff?

The Project components discussed in this report would add structures at various locations, including (1) new diversion structures at TP1, (2) two new pump stations at the SIWTF, and (3) a new pump station at the Blanco Drain. Up to 1,000 sq-ft of impervious surface may be added at each site, and runoff from the new hardscape would be directed to existing drainage structures or channels. The soils at these sites are Type C (runoff coefficient >80), so the increase in runoff will be small and within the available existing drainage system conveyance capacity. Runoff from the SIWTF TP1 site and Blanco Drain would be diverted to the Project. No impact is expected under this criterion.

d. Would the project place within a 100-year flood hazard area structures that would impede or redirect flood flows?

The Project would not make physical changes to the Salinas River, but it would add a diversion pump station on the Blanco Drain adjacent to an existing pump station and new pump stations at the SIWTF. All of these would be located within 100-year flood hazard areas. The proposed Blanco Drain pump station intake would be located at the channel bottom, and would be configured to not alter the conveyance capacity of the Blanco Drain. The pump stations within flood hazard areas would be configured with submersible pumps and elevated electrical controls so that they are not affected by occasional inundation. They should not require padded sites requiring revisions to the flood hazard maps.

Data from USGS Gage 11152500

Estimate based on gaged flow plus estimated inflows from SIWTF, Salinas Stormwater and Blanco Drain

**Total:** **7325**

Reflects recorded diversions at the SRDF

**Groundwater Recharge Project**

**Estimated No. Days with Flow of 60 cfs or Higher, Salinas River below SRDF, Diverting Ag Wash Water and Stormwater**

Data from USGS Gage 11152500

Estimate based on gaged flow plus estimated inflows from SIWTF, Salinas Stormwater and Blanco Drain

**Total:** **8083**

Reflects recorded diversions at the SRDF

**Groundwater Recharge Project**

**Estimated No. Days with Flow of 72 cfs or Higher, Salinas River below SRDF, Diverting at SIWTF, TP1 and Blanco Drain (2.99 cfs)**

Data from USGS Gage 11152500

Estimate based on gaged flow plus estimated inflows from SIWTF, Salinas Stormwater and Blanco Drain

**Total: 7971**

Reflects recorded diversions at the SRDF

**Groundwater Recharge Project**

**Estimated No. Days with Flow of 72 cfs or Higher, Salinas River below SRDF, Diverting at SIWTF, TP1 and Blanco Drain (6 cfs)**

Data from USGS Gage 11152500

Estimate based on gaged flow plus estimated inflows from SIWTF, Salinas Stormwater and Blanco Drain

**Total: 7960**

Reflects recorded diversions at the SRDF

**Scenario Notes:**

**Case 0:** Base Condition for Salinas River just downstream of Blanco Drain.
Flow = USGS Speckels, plus SIWTF outflow to River, plus Salinas Stormwater outfall,
plus inflows from Blanco Drain, minus SRDF (rubber dam) diversions and stormwater capture.

No diversions of Salinas stormwater or SIWTF water.
No diversions from Blanco Drain.
Rubber dam diversions 2010-2013 are balanced by extra flow at Spreckels.

**Case 1:** Divert both Salinas stormwater and SIWTF water.
No diversions from Blanco Drain.
Rubber dam diversions 2010-2013 are balanced by extra flow at Spreckels.

**Case 2:** Divert both Salinas stormwater and SIWTF water.
Divert up to 2.99 cfs from Blanco Drain.
Rubber dam diversions 2010-2013 are balanced by extra flow at Spreckels.

**Case 3:** Divert both Salinas stormwater and SIWTF water.
Divert up to 4.6 cfs from Blanco Drain.
Rubber dam diversions 2010-2013 are balanced by extra flow at Spreckels.

**Percentile Results:**
The flow with the nth percentile rank.
The 1.0 percetile flow is the highest daily flow.
The 0.50 percentile flow is the median daily flow.
The 0.01 percentile flow is exceeded 99% of the time (blank if 0.0 cfs).

**Daily Flow Data**
All daily results, sorted by date

**Data by month**
All daily results, sorted by month
Monthly Percentile ranking calcs, starting in column O

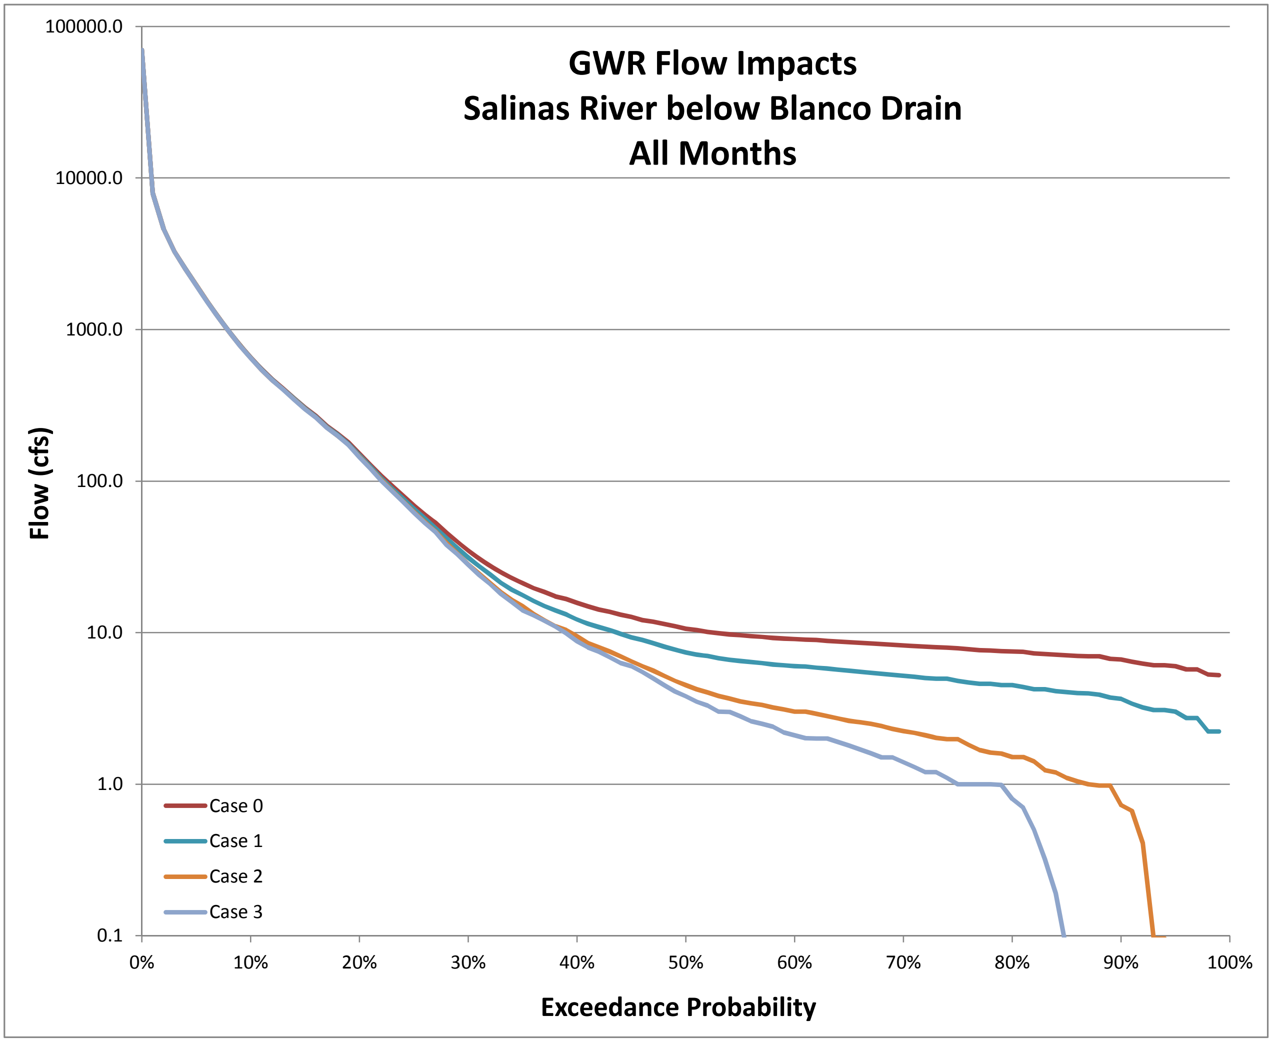
Case 0: No diversions (Base Condition).
Case 1: Divert both Salinas Stormwater and SIWTF; No Blanco Drain diversions.
Case 2: Divert both Salinas Stormwater and SIWTF; Divert up to 2.99 cfs from Blanco Drain.
Case 3: Divert both Salinas Stormwater and SIWTF; Divert up to 4.6 cfs from Blanco Drain.



**Case 0** No diversions (Base Condition).

**Case 1** Divert both Salinas Stormwater and SIWTF; No Blanco Drain diversions.

**Case 2** Divert both Salinas Stormwater and SIWTF; Divert up to 2.99 cfs from Blanco Drain.

**Case 3** Divert both Salinas Stormwater and SIWTF; Divert up to 4.6 cfs from Blanco Drain.

Note:

Measurement point for all cases is Salinas River just downstream of confluence with Blanco Drain.

SRDF diversions (from Salinas River behind rubber dam) occurred 2010-2013 for all cases above;
SRDF diversions balance extra flow at Spreckels during this period.

Total flow is the sum of the Salinas R. at Spreckels (USGS gage) plus storm runoff, plus SIWTF inflows, plus flow in from Blanco Drain, minus SRDF diversions and stormwater capture.

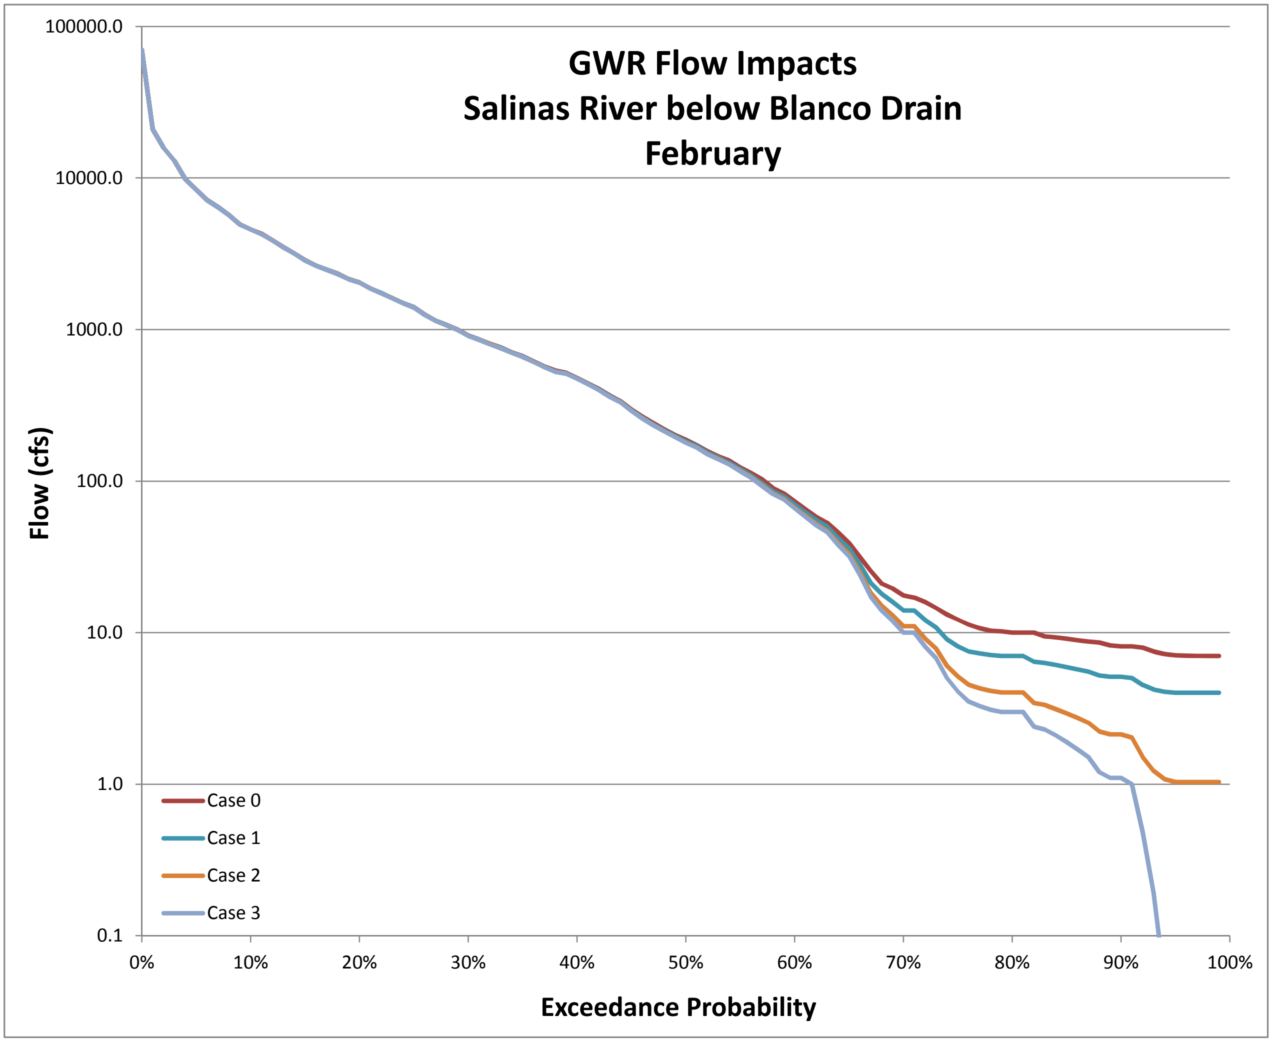
Case 0: No diversions (Base Condition).
Case 1: Divert both Salinas Stormwater and SIWTF; No Blanco Drain diversions.
Case 2: Divert both Salinas Stormwater and SIWTF; Divert up to 2.99 cfs from Blanco Drain.
Case 3: Divert both Salinas Stormwater and SIWTF; Divert up to 4.6 cfs from Blanco Drain.



**Case 0** No diversions (Base Condition).

**Case 1** Divert both Salinas Stormwater and SIWTF; No Blanco Drain diversions.

**Case 2** Divert both Salinas Stormwater and SIWTF; Divert up to 2.99 cfs from Blanco Drain.

**Case 3** Divert both Salinas Stormwater and SIWTF; Divert up to 4.6 cfs from Blanco Drain.

Note:

Measurement point for all cases is Salinas River just downstream of confluence with Blanco Drain.

SRDF diversions (from Salinas River behind rubber dam) occurred 2010-2013 for all cases above;
SRDF diversions balance extra flow at Spreckels during this period.

Total flow is the sum of the Salinas R. at Spreckels (USGS gage) plus storm runoff, plus SIWTF inflows, plus flow in from Blanco Drain, minus SRDF diversions and stormwater capture.

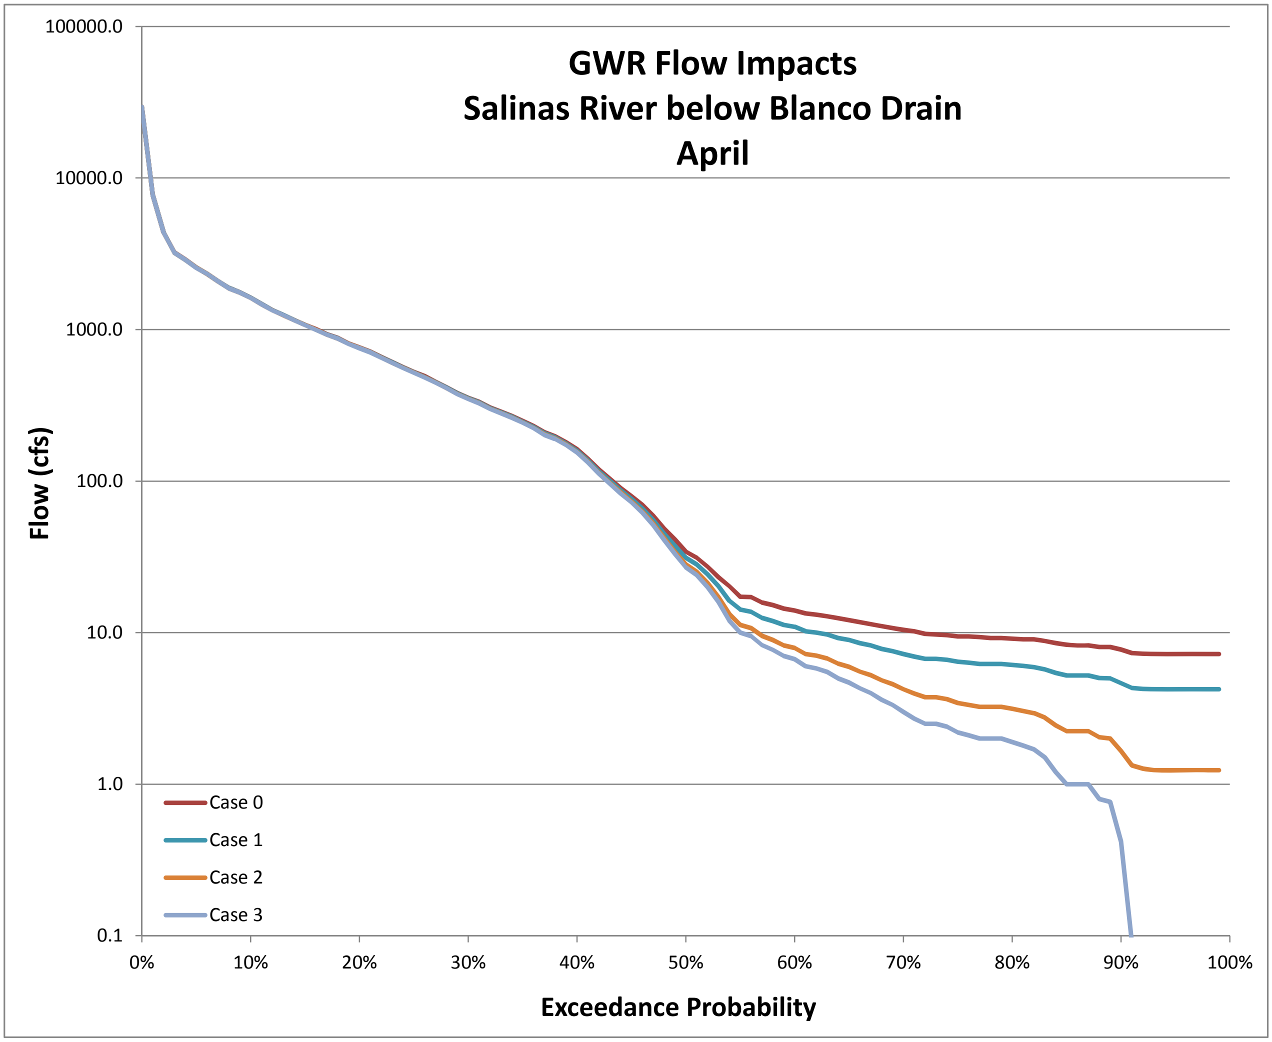
Case 0: No diversions (Base Condition).
Case 1: Divert both Salinas Stormwater and SIWTF; No Blanco Drain diversions.
Case 2: Divert both Salinas Stormwater and SIWTF; Divert up to 2.99 cfs from Blanco Drain.
Case 3: Divert both Salinas Stormwater and SIWTF; Divert up to 4.6 cfs from Blanco Drain.



**Case 0** No diversions (Base Condition).
**Case 1** Divert both Salinas Stormwater and SIWTF; No Blanco Drain diversions.
**Case 2** Divert both Salinas Stormwater and SIWTF; Divert up to 2.99 cfs from Blanco Drain.
**Case 3** Divert both Salinas Stormwater and SIWTF; Divert up to 4.6 cfs from Blanco Drain.

Note:
Measurement point for all cases is Salinas River just downstream of confluence with Blanco Drain.

SRDF diversions (from Salinas River behind rubber dam) occurred 2010-2013 for all cases above;
SRDF diversions balance extra flow at Spreckels during this period.

Total flow is the sum of the Salinas R. at Spreckels (USGS gage) plus storm runoff, plus SIWTF inflows, plus flow in from Blanco Drain, minus SRDF diversions and stormwater capture.

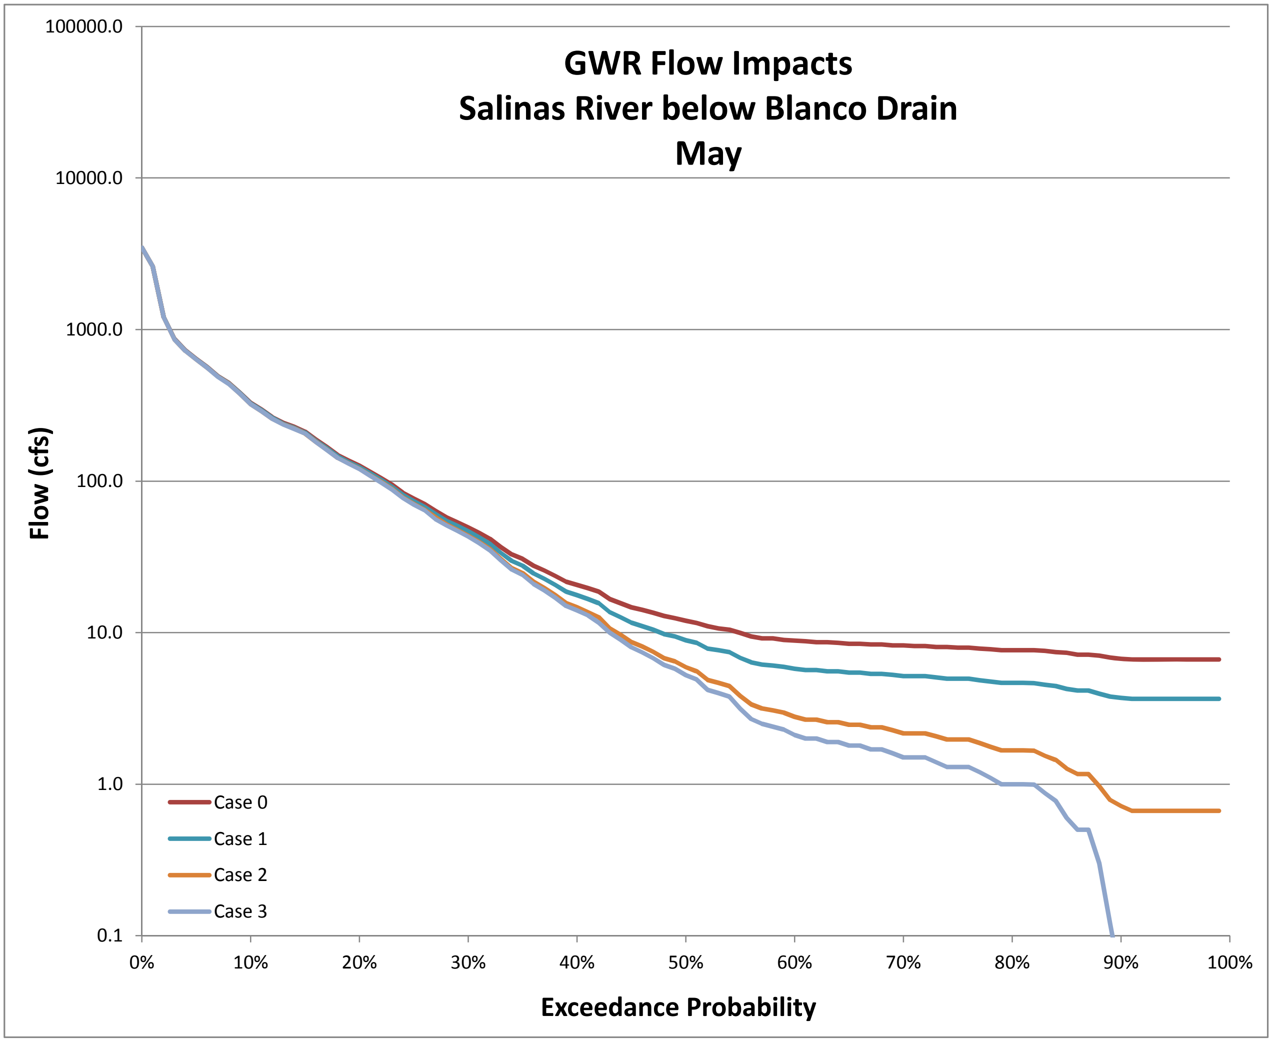
Case 0: No diversions (Base Condition).
Case 1: Divert both Salinas Stormwater and SIWTF; No Blanco Drain diversions.
Case 2: Divert both Salinas Stormwater and SIWTF; Divert up to 2.99 cfs from Blanco Drain.
Case 3: Divert both Salinas Stormwater and SIWTF; Divert up to 4.6 cfs from Blanco Drain.



**Case 0** No diversions (Base Condition).
**Case 1** Divert both Salinas Stormwater and SIWTF; No Blanco Drain diversions.
**Case 2** Divert both Salinas Stormwater and SIWTF; Divert up to 2.99 cfs from Blanco Drain.
**Case 3** Divert both Salinas Stormwater and SIWTF; Divert up to 4.6 cfs from Blanco Drain.

Note:
Measurement point for all cases is Salinas River just downstream of confluence with Blanco Drain.

SRDF diversions (from Salinas River behind rubber dam) occurred 2010-2013 for all cases above;
SRDF diversions balance extra flow at Spreckels during this period.

Total flow is the sum of the Salinas R. at Spreckels (USGS gage) plus storm runoff, plus SIWTF inflows, plus flow in from Blanco Drain, minus SRDF diversions and stormwater capture.

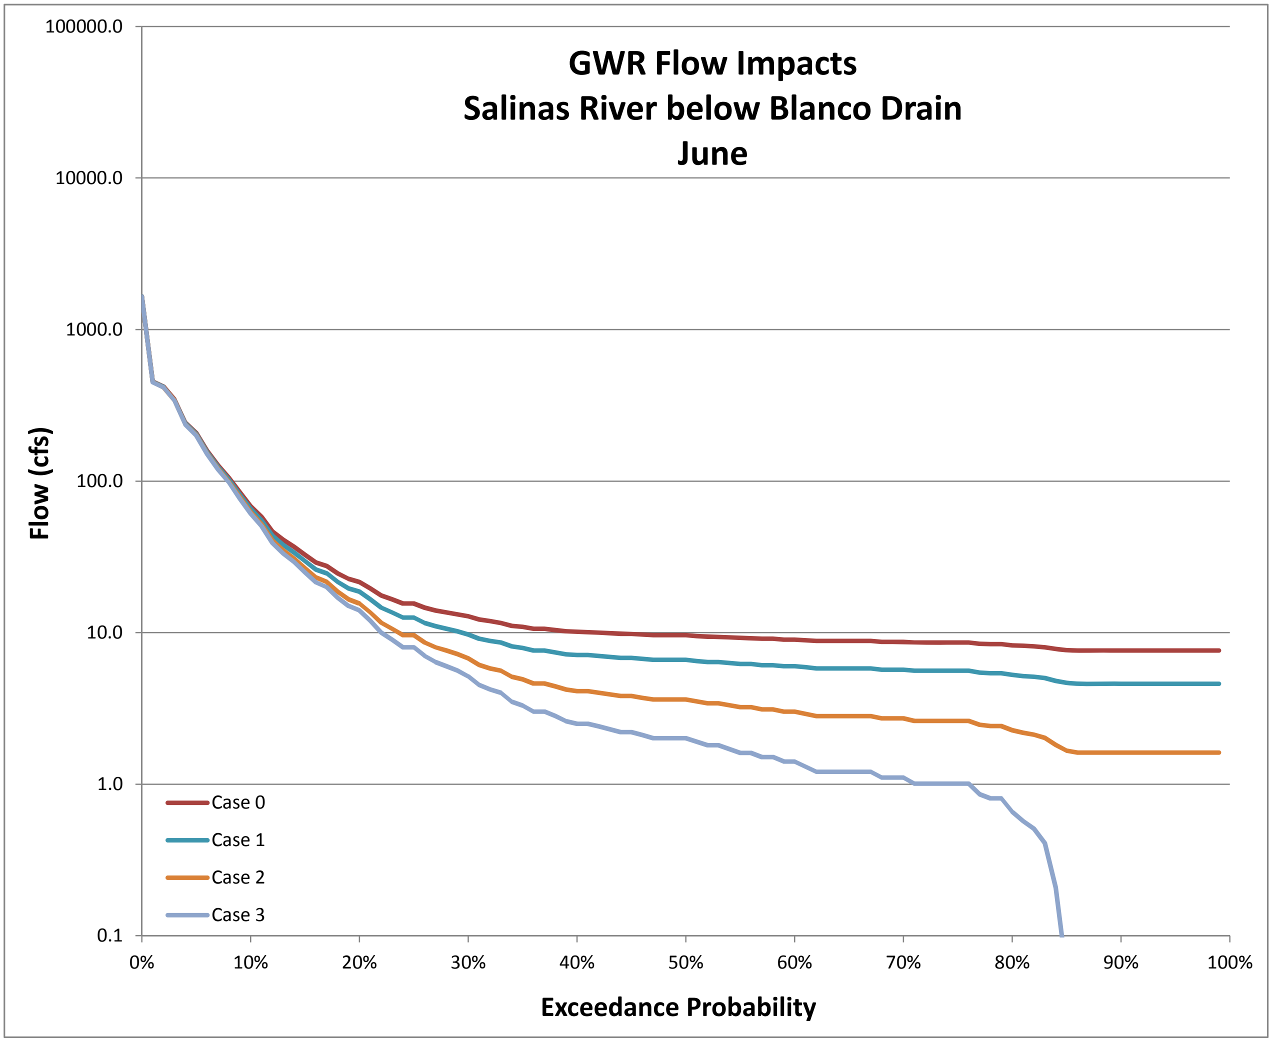
Case 0: No diversions (Base Condition).
Case 1: Divert both Salinas Stormwater and SIWTF; No Blanco Drain diversions.
Case 2: Divert both Salinas Stormwater and SIWTF; Divert up to 2.99 cfs from Blanco Drain.
Case 3: Divert both Salinas Stormwater and SIWTF; Divert up to 4.6 cfs from Blanco Drain.



**Case 0** No diversions (Base Condition).
**Case 1** Divert both Salinas Stormwater and SIWTF; No Blanco Drain diversions.
**Case 2** Divert both Salinas Stormwater and SIWTF; Divert up to 2.99 cfs from Blanco Drain.
**Case 3** Divert both Salinas Stormwater and SIWTF; Divert up to 4.6 cfs from Blanco Drain.

Note:
Measurement point for all cases is Salinas River just downstream of confluence with Blanco Drain.

SRDF diversions (from Salinas River behind rubber dam) occurred 2010-2013 for all cases above;
SRDF diversions balance extra flow at Spreckels during this period.

Total flow is the sum of the Salinas R. at Spreckels (USGS gage) plus storm runoff, plus SIWTF inflows,
plus flow in from Blanco Drain, minus SRDF diversions and stormwater capture.

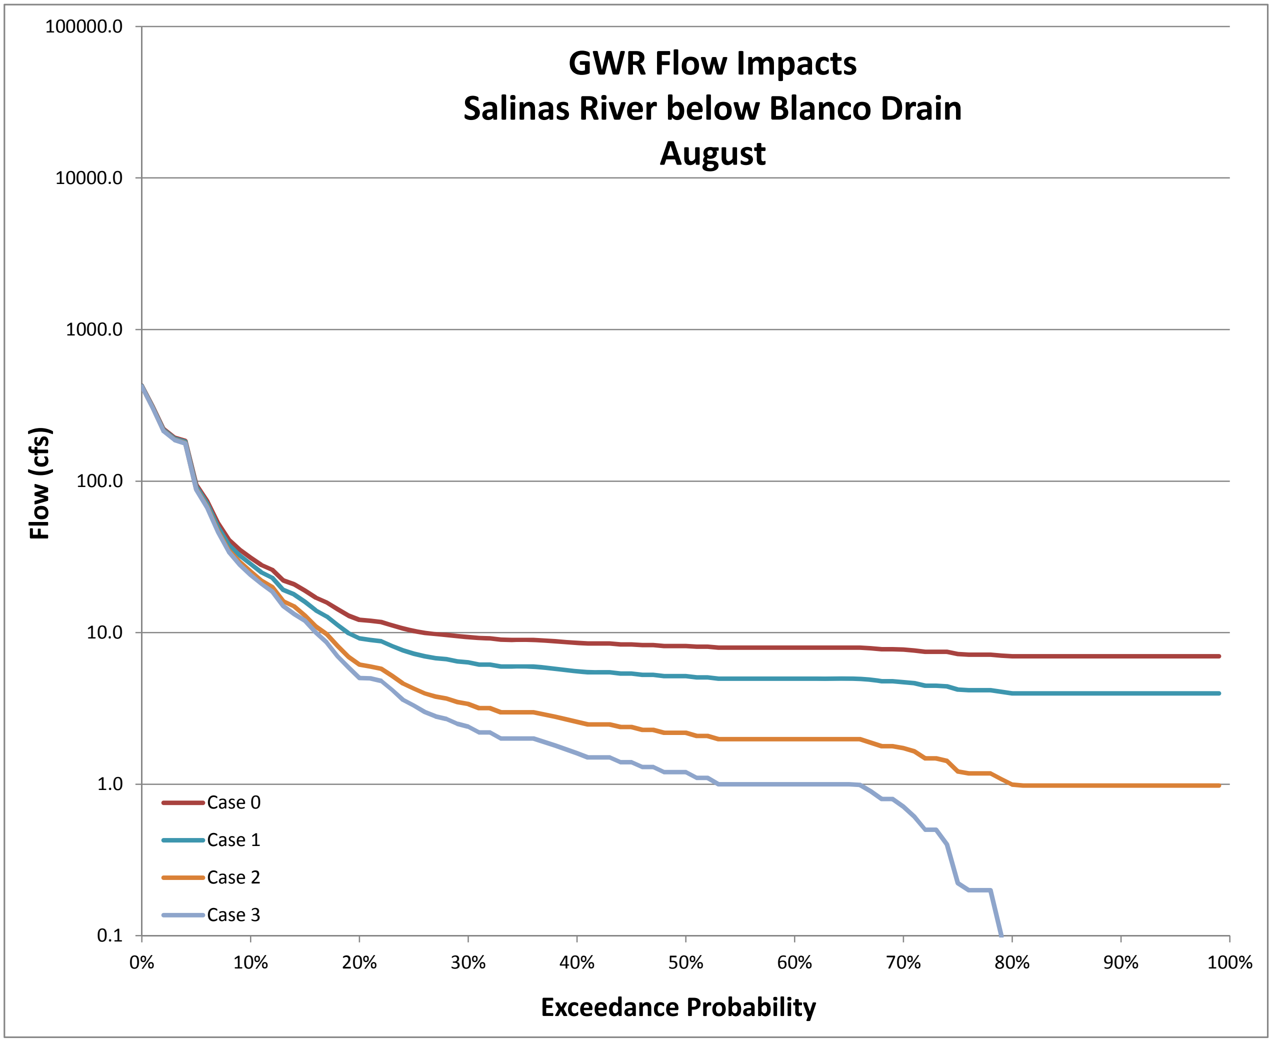
Case 0: No diversions (Base Condition).
Case 1: Divert both Salinas Stormwater and SIWTF; No Blanco Drain diversions.
Case 2: Divert both Salinas Stormwater and SIWTF; Divert up to 2.99 cfs from Blanco Drain.
Case 3: Divert both Salinas Stormwater and SIWTF; Divert up to 4.6 cfs from Blanco Drain.



**Case 0** No diversions (Base Condition).

**Case 1** Divert both Salinas Stormwater and SIWTF; No Blanco Drain diversions.

**Case 2** Divert both Salinas Stormwater and SIWTF; Divert up to 2.99 cfs from Blanco Drain.

**Case 3** Divert both Salinas Stormwater and SIWTF; Divert up to 4.6 cfs from Blanco Drain.

Note:

Measurement point for all cases is Salinas River just downstream of confluence with Blanco Drain.

SRDF diversions (from Salinas River behind rubber dam) occurred 2010-2013 for all cases above; SRDF diversions balance extra flow at Spreckels during this period.

Total flow is the sum of the Salinas R. at Spreckels (USGS gage) plus storm runoff, plus SIWTF inflows, plus flow in from Blanco Drain, minus SRDF diversions and stormwater capture.

## Summary of Reclamation Ditch Yield Study

The Monterey Peninsula Water Management District (MPWMD) and the Monterey Regional Water Pollution Control Agency (MRWPCA) are jointly sponsoring the proposed Pure Water Monterey Groundwater Replenishment Project (Proposed Project), a water supply project that will serve northern Monterey County. The project will provide purified water for recharge of the Seaside Groundwater Basin that serves as drinking water supply, and recycled water to augment the existing Castroville Seawater Intrusion Project agricultural irrigation supply. One of the proposed sources of water supply to be developed for this project is surface water flowing in the Reclamation Ditch and Tembladero Slough. The purpose of this study was to (1) analyze water availability in the Reclamation Ditch, (2) provide an engineering analysis of the potential yields and the infrastructure required to capture and convey those flows to the Proposed Project, and (3) assess the potential project impacts on hydrology and water quality in the Reclamation Ditch and Tembladero Slough.

The Reclamation Ditch watershed is approximately 157 square miles that includes headlands, agricultural areas, the City of Salinas and portions of Castroville and Prunedale. Summer flows are predominantly agricultural tile drainage. Winter flows include runoff from throughout the basin.

Yields were estimated for two diversion points, the Reclamation Ditch at Davis Road and Tembladero Slough at Castroville. These locations were selected based on their proximity to existing wastewater collection facilities, which may be used to convey the flows to the MRWPCA Regional Treatment Plant. Maximum diversion rates were based upon the average historic flows in the Reclamation Ditch, the available conveyance capacity in the existing wastewater collection systems and assumed minimum in-stream flows rates to maintain existing habitat. Water rights permit applications for diversions less than 3 cfs may be processed more quickly than applications requesting higher diversion rates, so the Proposed Project includes an initial phase with 2.99 cfs diversions, and a second phase with higher diversion rates. The estimated annual yields are shown in Table S-1, below.

**Table S-1: Estimated Annual Diversions**

| **Proposed Project, Initial Water Rights Permits** | | |
|---|---|---|
| **Location** | **Diversion Rate (cfs)** | **Annual Diversion (AF)** |
| Davis Road | 2.99 | 1,088 |
| Castroville | 2.99 | 1,162 |
| Total | | 2,250 |
| **Proposed Project, Ultimate Water Rights Permits** | | |
| **Location** | **Diversion Rate (cfs)** | **Annual Diversion (AF)** |
| Davis Road | 6.0 | 1,521 |
| Castroville | 2.99 | 1,134 |
| Total | | 2,655 |

The yields in Table S-1 assume a minimum in-stream flow requirement of 0.69 cfs at Davis Road during the months of June through November, and 2.0 cfs during the months of December through May when higher flows are required for fish migration. A minimum in-stream flow of 1 cfs was assumed for the Tembladero Slough at Castroville in all months.

Flows in the Reclamation Ditch and Tembladero Slough below the proposed diversion facilities were estimated using a mass balance model, and a statistical analysis was performed on the results. Diverting stream flows to the Proposed Project would reduce average monthly flows in the Reclamation Ditch by up to 79% during the dry summer months, and by 12% to 40% during the wet winter months.

# Section 1 - Introduction

## 1.1 Project Description

The Monterey Peninsula Water Management District (MPWMD) and the Monterey Regional Water Pollution Control Agency (MRWPCA) are jointly sponsoring the proposed Pure Water Monterey Groundwater Replenishment Project (Proposed Project), a water supply project that will serve northern Monterey County. The project will provide purified water for recharge of the Seaside Groundwater Basin that serves as drinking water supply, and recycled water to augment the existing Castroville Seawater Intrusion Project agricultural irrigation supply.

Source water for the project would include agricultural wash water from the City of Salinas Industrial Wastewater Collection System, stormwater from MRWPCA member cities, secondary-treated effluent from the MRWPCA Regional Treatment Plant, and surface water diverted from the Reclamation Ditch, Tembladero Slough and Blanco Drain. Water supplied to the Proposed Project would undergo primary and secondary treatment at the existing Regional Treatment Plant. The portion used for groundwater recharge would then undergo advanced treatment at a new facility to be located at the MRWPCA site, and then be conveyed to the Seaside Groundwater Basin for injection. The portion used for agricultural irrigation would undergo tertiary treatment at the existing Salinas Valley Reclamation Plant, and distribution through the Castroville Seawater Intrusion Project system.

The MRWPCA provides wastewater treatment for municipalities along the Monterey Bay from Pacific Grove north to Moss Landing, and inland to the City of Salinas. Wastewater is collected in an interceptor pipeline system and conveyed to the Regional Treatment Plant (RTP), located two miles north of the City of Marina. A large portion of this incoming flow is tertiary treated and used for unrestricted agricultural irrigation within the Castroville Seawater Intrusion Project system in the northern Salinas Valley. Flow that is not sent to the tertiary treatment system is discharged through an outfall to Monterey Bay after receiving secondary treatment. The RTP has an average dry weather design capacity of 29.6 million gallons per day (mgd) and a peak wet weather design capacity of 75.6 mgd. It currently receives and treats approximately 17 to 18 mgd of average dry weather flow and therefore has capacity to treat additional flows. The interceptor pipeline system also has currently unused or excess conveyance capacity. Most of the new source waters would be conveyed to the RTP using the existing wastewater collection system.

Transfers of source water flowing in known and definite channels, such as the Reclamation Ditch, to the GWR project would be a consumptive use that may require an appropriative permit from the State Water Resources Control Board (SWRCB). The purpose of this study was to analyze water availability in the Reclamation Ditch and provide an engineering analysis of the potential yields and the infrastructure required to capture and convey those flows to the RTP. The study also provides a preliminary analysis of the water quality and hydrologic impacts of the

Proposed Project. This hydrologic information and analysis may then be used in a permit application to the SWRCB.

### 1.2 Water Source Description

The Reclamation Ditch watershed is approximately 157 square miles that includes headlands, agricultural areas, the City of Salinas and portions of Castroville and Prunedale. The Ditch, created between 1917 and 1920, is a network of excavated earthen channels used to drain surface runoff generated in the watershed. It captures Alisal Creek at Smith Lake, southeast of the City of Salinas, Gabilan and Natividad Creeks within the City at Carr Lake, and Santa Rita Creek west of the City. The Ditch is a major drainage channel that flows from east to west through Salinas and continues west where it drains into Tembladero Slough, then the Old Salinas River Channel, and ultimately into Moss Landing Harbor through the Potrero Road Tide Gates. See Figures A-1, Reclamation District No. 1665, and A-2, Reclamation Ditch Watershed and Zone 9 Boundary.

The Reclamation Ditch is perennial downstream of agricultural and urban development. According to USGS records, flow west of Salinas at the San Jon Road gage only ceased on three days between 1971 and 1985, and on those days, standing water was probably still present throughout most of the Reclamation Ditch. The presence of standing water is reflective of historical conditions, since the area was a system of lakes. However, the presence of dry-season flow is a consequence of dry-season urban discharges and agricultural tailwater[1]. Annual runoff at the USGS gage station at San Jon Road for Water Years 1971-2012 has averaged 11,220 AFY. This average has declined by almost a third in recent years as water conservation practices have reduced the amount of agricultural irrigation. Monthly average flows for the San Jon gage are tabulated below. The gage was inactive from March 1986 to May 2002. Recorded flows prior to February 1986 reflect the maximum daily flow[2] and not the true daily mean. In the dry season months (June to October), the daily maximum and average flows are nominally equal, but in the wet months, the data will skew slightly higher than using true daily average flows.

Summer flows in the Reclamation Ditch come from urban runoff and agricultural return flows. The primary source of this water is groundwater from the Salinas Valley Groundwater Basin. Approximately 12,000 acres in north Monterey County receive recycled water for agricultural irrigation under the Castroville Seawater Intrusion Project (CSIP), which is intended to reduce well pumping along the coast. The MRWPCA operates the Salinas Valley Reclamation Plant adjacent to the RTP to produce tertiary treated and disinfected recycled water for this system. About half of the CSIP service area is tributary to the Reclamation Ditch. Since 2010, Salinas River water has also been included in the CSIP deliveries, as discussed below.

The Reclamation Ditch is maintained by the Monterey County Water Resources Agency (MCWRA). The Ditch is a trapezoidal channel which connects a series of natural creeks and seasonal lakes. Flows from some tributary channels, such as Markley Swamp, are controlled by flap gates to prevent high seasonal flows from backing up into these side channels. The lakes are FEMA floodways for major storm events, but are used for irrigated agriculture during the majority of the time. In several locations, the MCWRA operates pump stations to drain low points along the tributary channels to improve the drainage for agricultural use. There are no gates or control structures within the main stem of the Reclamation Ditch system other than the tides gates at Potrero Road.

[3] USGS Water-Data Report 2012, 11152650 Reclamation Ditch near Salinas, CA

**Figure 1.1: Reclamation Ditch at Alisal Street**

The Salinas Valley Groundwater Basin is the primary source of water supply in the Salinas Valley. The Salinas River recharges the aquifer through percolation in the Upper Valley and Forebay sub-areas (see figure A-3). Historically, the river flowed seasonally, with little to no flows in the late summer months. To augment the natural aquifer recharge, the MCWRA operates two reservoirs in the upper valley: San Antonio Reservoir (water right permit 12261) and Nacimiento Reservoir (water right permits 10137 and 21089). Water is released from these reservoirs to maintain year-round flow in the Salinas River for aquifer recharge. Permits 12261 and 10137 allow MCWRA to redivert flows released to the Salinas River at the Salinas River Diversion Facility (SRDF), located near the MRWPCA RTP. This water is currently used to augment the recycled water supplies for the CSIP. The permit for SRDF operation requires certain seasonal flow releases for habitat maintenance in the main-stem river channel and in the Salinas River Lagoon. Of note, during summer operation of the SRDF, a minimum bypass flow of 2 cfs be maintained for the Salinas Lagoon.

During the summer months, the Salinas River flows into the Old Salinas River Channel through a gated culvert at the Salinas Lagoon. Direct discharge to the ocean is blocked by a seasonal sand bar which forms across the mouth of the Salinas Lagoon due to wave and tidal action in the

Monterey Bay. Discharge from the lagoon through the culvert is limited to 100 cfs[4]. The Old Salinas River channel is controlled by tide gates at Potrero Road in Moss Landing. River flows combine with Tembladero Slough flows approximately 1.2-miles above the tide gates. During high winter flows in the Salinas River, the sand bar breaches and the river flows directly to the Bay. When this occurs, MCWRA closes the slide gate to the Old Salinas River, and only Tembladero Slough flows through the Potrero Road tide gates.

The water quality in the Reclamation Ditch is generally poor, containing high levels of nitrates and pesticides and low levels of dissolved oxygen. The Reclamation Ditch (Salinas Reclamation Canal) and all of its tributary streams are on the California Listing of Water Quality Limited Stream Segments, as reported under Section 303(d) of the Federal Clean Water Act. A summary matrix of 303(d) listed streams is at Table B-1. Water quality is discussed in greater detail in Section 4 of the Report.

Aquatic habitats within the Reclamation Ditch system are poor. In addition to the poor water quality, the Ditch is generally maintained as a drainage canal without tree canopy. The adjacent agricultural lands are used for growing table crops (leafy greens, berries and artichokes). The growers prevent vegetation from establishing along the Ditch banks to discourage birds and rodents from nesting near their fields. Within the City of Salinas, the Reclamation Ditch is an urban watercourse with steep sides and numerous pipe culverts or bridges with lined inverts. Three of the tributary streams, Alisal, Gabilan and Natividad Creek, extend beyond the agricultural areas into the Gabilan Range. The upper portions of these streams are in a more natural state, although the adjacent lands are used for ranching and cattle grazing. Rainbow trout may have been introduced to the upper reaches of Gabilan Creek for an unknown period ending in 1958[5]. Any fish migration from the ocean to these upper reaches would occur in the winter months (November to March) during high seasonal flows, and downstream migration of juvenile fish would occur in the spring (March to May). These creeks are general dry above Old Stage Road in Salinas during the summer months.

# Section 2 - Yield Estimation

## 2.1 Methodology

As stated in the Project Description, water supplies for the GWR Project will be conveyed to the RTP using existing excess capacity in the MRWPCA interceptor system. Potential diversion points along the Reclamation Ditch were identified that were in close proximity to existing wastewater collection and conveyance facilities. Estimates of stream flow capture from the Reclamation Ditch system were made for two locations: the Reclamation Ditch at Davis Road and Tembladero Slough at the MRWPCA Castroville pump station. The Davis Road location is adjacent to a City of Salinas 54-inch sanitary sewer main which flows to the MRWPCA Salinas Pump Station.

Flow data for the Reclamation Ditch at San Jon Road (USGS Gage No 11152650) was used as the basis of this analysis. A second stream gage exists on Gabilan Creek well above Carr Lake. This gage was not included in the estimate because of its distance from the diversion points.

The drainage basin above the USGS Gage is listed as 53.2 square-miles, which is incorrect. In the earlier Reclamation Ditch Zone 9 Report, Schaaf & Wheeler calculated the sub-basin sizes for the entire Reclamation Ditch watershed (see figure A-4). Based on that data, the basin size above the USGS gage is 109.4 square-miles. The drainage basin above the proposed diversion point on the Reclamation Ditch at Davis Road is 102.5 square-miles, or 93.7% of the gaged area. The drainage basin above the MRWPCA Castroville Pump Station is 152.7 square-miles, or 140% of the gaged area.

Historic mean daily flows at the two diversion points were calculated by scaling the recorded flows at San Jon Road by the factors listed above (see Appendix B, Tables B-2 and B-3). For the Davis Road diversion point, the two areas are nearly the same and therefore the estimate is fairly reliable. For the Castroville diversion point, the difference in basin size is significant, and the additional area is predominantly irrigated agriculture, which may result in higher tile drain return flows than this method would indicate. The scaled value may therefore be considered conservatively low.

Diversions at the two locations were calculated on a daily basis using the following formulas:

> Available Flow = (Daily Flow) - (In-stream Flow Target)
>
> IF (Available Flow) < 0, Daily Diversion = 0
>
> IF (Available Flow) <= (Target Diversion), Daily Diversion = Available Flow
>
> IF (Available Flow) > (Target Diversion), Daily Diversion = Target Diversion

In-stream flow targets for habitat maintenance from 0.67 cfs to 2 cfs were used in the yield estimations, as discussed in Section 2.2. Daily diversions were converted to acre-feet and summed by month.

Target diversion rates were based upon available flows and the existing conveyance capacity in the sanitary sewer system. At the Davis Road diversion point, there is an existing 54-inch City of Salinas sanitary sewer main (see figure A-5), which conveys flows to the MRWPCA Salinas Pump Station (see figure A-6). The full pipeline profile was not available, but the profile of downstream segments showed slopes of 0.0006 and greater. We assumed that the limiting segment in the pipeline would have a slope of 0.0003, which would allow gravity flow at 2.44 ft/s with d/D of 0.9. This equates to a maximum Q of 36.3 cfs, or 23.5 mgd. The 54-inch sanitary sewer was metered in summer 2010 as part of a capacity study for the MRWPCA Salinas Pump Station[6]. The average dry weather flow in that main was about 7 mgd. The diurnal peaking factor (per the City's 2004 SSMP) is 1.6, so the Peak Dry Weather Flow (PDWF) is 11.2 mgd or 17.3 cfs. That leaves up to 19 cfs of conveyance capacity within the gravity main to carry dry weather flows from the Reclamation Ditch. This pipeline is projected to approach full capacity as the City is built-out[7], but that may take several decades to occur. The Salinas Pump Station has a rated capacity of 35.4 MGD and sees PDWF of 19 MGD[8], leaving 16.4 MGD of available conveyance capacity.

Mean summer flows in the Reclamation Ditch are typically less than 5 cfs at San Jon Rd (period May to October, see Table 2-1). Average daily flows exceed 3 cfs about 30% of the time, and exceed 6 cfs only 5% of the time (see Table 2-2). Therefore, 6 cfs was used as the maximum diversion rate for the Davis Road site. Diversions were calculated for the Reclamation Ditch at Davis Road using diversion targets from 1.0 cfs to 6.0 cfs, assuming an in-stream flow requirement from 0.67 to 2.0 cfs to maintain aquatic and riparian habitats. The permitting process for a water right diversion under 3 cfs is shorter than for a larger water right, so the Proposed Project assumes an initial water right diversion permit at 2.99 cfs, and an ultimate water right allowing diversions at up to 6 cfs. The annual yield results are presented in Table 2-3, below. Monthly diversion estimates are shown in Table B-4.

[9] Source: USGS gage 11152650, daily average flows in cfs

**Table 2-3: Estimated Yields from the Reclamation Ditch at Davis Road**

| Bypass and Diversion Targets | Annual Diversion (AF) |
|---|---|
| Bypass 1 cfs, Max Diversion 1 cfs | 541.2 |
| Bypass 1 cfs, Max Diversion 2 cfs | 906.2 |
| Bypass 1 cfs, Max Diversion 2.9 cfs | 1,134.7 |
| Bypass 1 cfs, Max Diversion 2.99 cfs | 1,153.8 |
| Bypass 1 cfs, Max Diversion 3 cfs | 1,155.9 |
| Bypass 1 cfs, Max Diversion 4 cfs | 1,337.5 |
| Bypass 1 cfs, Max Diversion 5 cfs | 1,484.0 |
| Bypass 1 cfs, Max Diversion 6 cfs | 1,610.6 |
| Bypass 2 cfs, Max Diversion 2.99 cfs | 794.7 |
| Bypass 2 cfs, Max Diversion 6 cfs | 1185.7 |
| Bypass 0.67 cfs, Max Diversion 2 cfs | 1,014.3 |
| Bypass 0.67, Max Diversion 2.99 cfs | 1,295.6 |
| Bypass 0.67, Max Diversion 6 cfs | 1,783.2 |

The estimates above include diversions during wet winter months. Peak wet weather flows in the City's sanitary sewer system may not allow for capture of peak winter flows from the Reclamation Ditch (i.e., there may not be 6 cfs of available capacity in the collection system when there is 6 cfs available for diversion). The 6 cfs diversion rate was used for facility sizing, as discussed in Section 3.

At the Castroville diversion point on Tembladero Slough, the MRWPCA Castroville Pump Station has a rated capacity of 3.2 MGD. The peak dry weather flow is listed at 1.2 MGD, leaving 2 MGD of excess summer capacity, or 3.1 cfs. The peak wet weather flow is listed at 2.0 MGD, leaving 1.2 MGD of excess winter capacity, or 2.2 cfs. Diversions were calculated for Tembladero Slough using diversion targets from 2.2 cfs to 3.5 cfs, assuming an in-stream flow requirement of 1.0 cfs. The annual yield results are tabulated below. The Proposed Project assumes a diversion rate of 2.99 cfs to allow for the simpler water rights permitting process. Monthly diversion estimates are shown in Table B-5.

**Table 2-4: Estimated Yields from Tembladero Slough at Castroville**

| Bypass and Diversion Targets | Annual Diversion (AF) |
|---|---|
| Bypass 1 cfs, Max Diversion 2.2 cfs | 1,234.5 |
| Bypass 1 cfs, Max Diversion 2.5 cfs | 1,355.1 |
| Bypass 1 cfs, Max Diversion 2.9 cfs | 1,501.7 |
| Bypass 1 cfs, Max Diversion 2.99 cfs | 1,532.5 |
| Bypass 1 cfs, Max Diversion 3 cfs | 1,535.9 |
| Bypass 1 cfs, Max Diversion 3.5 cfs | 1,694.4 |

Estimates were also prepared for diverting at both stations concurrently. This option entails higher capital and operating costs, but the potential yields are higher because you can capture more of the lower basin flows from Santa Rita and Merritt Creeks. It also reduced the potential of not being able to capture high winter flows due to competition with City of Salinas peak wet weather flows in the municipal collection system. The annual yield results are tabulated below. Monthly diversion estimates are shown in Table B-6. As can be seen, more total flow is captured when the daily maximum diversion of 6 cfs is divided between the two sites. Even after increasing the in-stream bypass requirement to 2 cfs, the total annual diversion is higher than applying the 6 cfs target at the Davis Road site alone. In the final two estimates, seasonal in-stream flow targets of 0.67 cfs in the summer and 2.0 cfs in the winter were assumed, with the higher flows required in during the fish migration season, discussed below.

**Table 2-5: Estimated Yields from Two Diversion Locations**

| Bypass and Diversion Targets | Annual Diversion (AF) |
|---|---|
| Bypass 1 cfs, Max Diversion 2 cfs (net 4 cfs) | 1,834.1 |
| Bypass 1 cfs, Max Diversion 2.9 cfs (net 5.8 cfs) | 2,220.5 |
| Bypass 1 cfs, Max Diversion 2.99 cfs (net 5.98 cfs) | 2,252.0 |
| Bypass 1 cfs, Max Diversion 3 cfs (net 6 cfs) | 2,255.5 |
| Bypass 2 cfs, Max Diversion 3 cfs (net 6 cfs) | 1,770.5 |
| Bypass 1 cfs, Divert 6 cfs RD, 2.99 cfs TS (net 8.99 cfs) | 2,562.3 |
| Bypass 2 cfs, Divert 6 cfs RD, 2.99 cfs TS (net 8.99 cfs) | 2,049.6 |
| Seasonal Bypass, Div 2.99 cfs both sites (net 5.98 cfs) | 2,249.9 |
| Seasonal Bypass, Divert 6 cfs RD, 2.99 cfs TS (net 8.99 cfs) | 2,654.8 |

Notes:
Same diversion target at both sites, unless noted otherwise
Seasonal bypass targets: 0.69 cfs at Davis Rd (JUN-NOV), 2 cfs at Davis Rd (DEC-MAY), 1 cfs at Castroville (JAN-DEC)

## 2.2 In-Stream Flow Requirements

For the initial analysis, we assumed a minimum in-stream flow of 1 cfs must be maintained prior to making any diversions. This was based upon the typical minimum summer flow rate as recorded at the USGS gage 11152650 on the Reclamation Ditch. A minimum in-stream flow was not established in the documents reviewed, but habitats for some aquatic species were identified in the source reports.

**Figure 2.1: USGS Station 11152650 (flowing at 4.9 cfs)**

The USGS Gaging Station on the Reclamation Ditch uses a weir gage, as shown in Figure 2.1, above. The rating curve for this station is provided at Figure 2.2. A log-log plot is required to show the change in depth vs. flow at lower flow rates. As can be seen in the graph, the water level at the gaging station is 0.7 feet above the datum when the flow is 1 cfs. However, the gage datum is not the weir crest, so a flow of 1 cfs is only about 0.1 ft deep across the weir. As seen in the photograph, the water depths above and below the gaging weir are deeper, and the change in channel water level tracks with the recorded gage height. At 7 cfs, the gage height increases to 1.1 feet. Therefore, diverting at the maximum target of 6 cfs would, in the most extreme case (i.e., diverting 6 cfs and bypassing 1 cfs), reduce the water level in the channel by 0.4 feet. At higher flow rates, a 6 cfs flow reduction produces a smaller change in water depth.

**Figure 2.2: Rating Curve for USGS Station 11152650, log-log Plot[10]**

Figures 2.3 and 2.4, below, show the cumulative effects of diverting flows from the Reclamation Ditch. Tables B-7 and B-8 with the underlying data are included in Appendix B. In Figure 2.3, flows with no diversion at Davis Road are compared to flows after capturing up to 6 cfs with a 1 cfs minimum bypass. The flow reductions range from 15% in the winter months to 65% in the summer. Note that despite this flow reduction, the summer water surface would only be reduced by 0.4 feet. In Figure 2.4, the same comparison is made, but a 2 cfs minimum bypass is modeled. The summer flows would be reduced by only 40% under this scenario. Under the seasonal by-pass scenario (leaving the first 2 cfs in-stream from December through May, and leaving 0.69 cfs in-stream from June through November), the summer flow reduction reaches 79% when diverting up to 6 cfs at Davis Road.

The Tembladero Slough is tidally influenced from the Old Salinas River Channel up to Highway 183 in Castroville. The backwater condition caused by the tide gates would prevent measurable reductions in water levels throughout that reach. The potential change in water level in the Reclamation Ditch below the Davis Road diversion site should not affect riparian species along the creek banks, which are adapted to seasonally varying water levels.

[10] USGS Gaging Station website

**Figure 2.3: Flows Comparison for 6 cfs Diversion with 1 CFS Bypass**

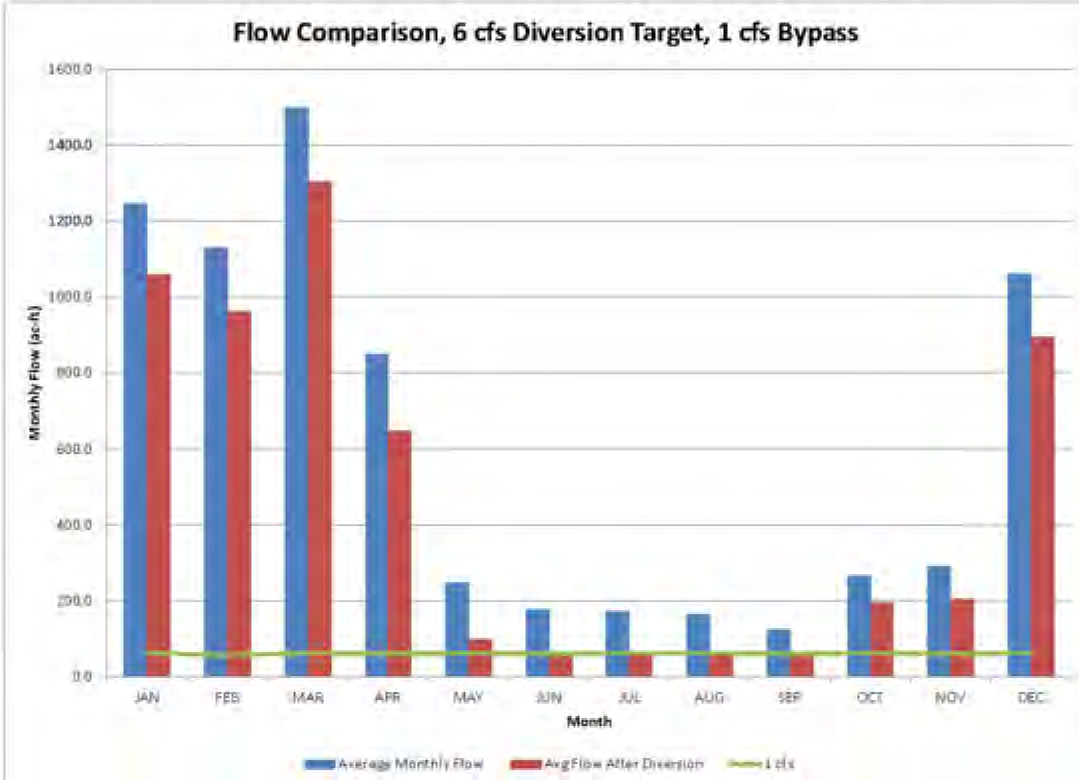

**Figure 2.4: Flows Comparison for 6 cfs Diversion with 2 CFS Bypass**

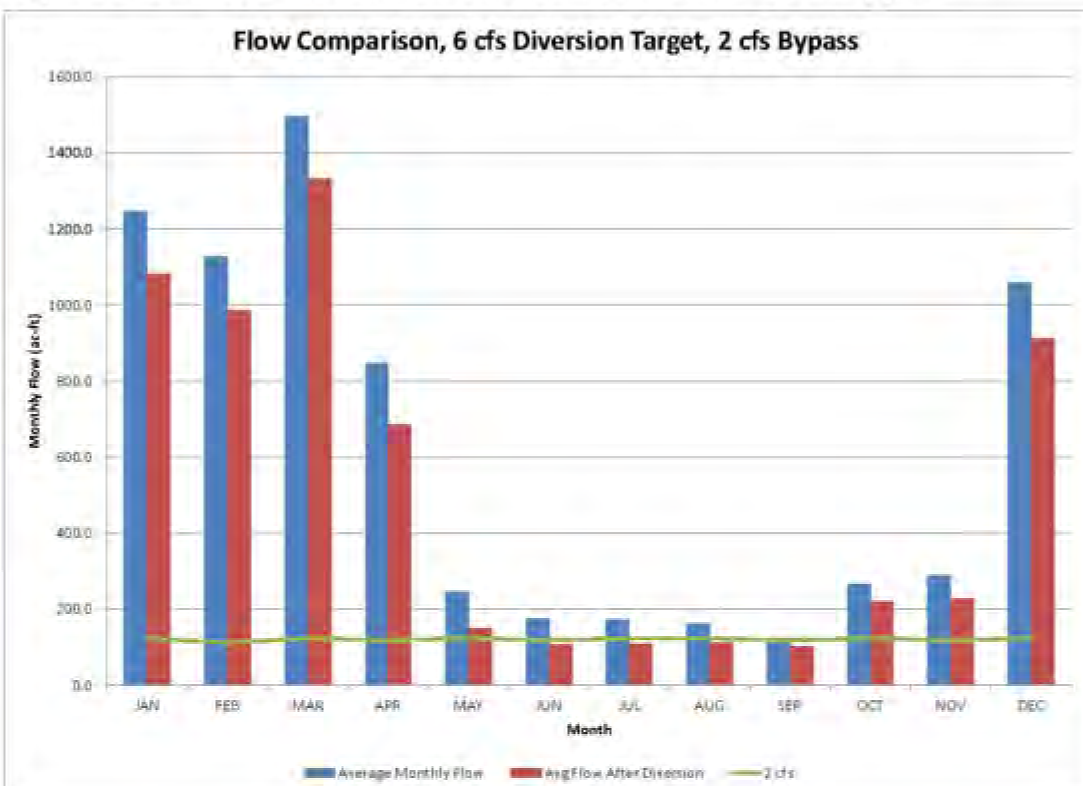


Reduced flows may affect migratory fish species which traverse the Tembladero Slough and Reclamation Ditch to and from Gabilan Creek, which has been identified as suitable habitat for South-Central California Coast Steelhead[11]. Objects in the channel bottom, such as the USGS stream gage or riprap placed for erosion control, present obstacles to fish passage at low flows but are submerged at higher flows. The steelhead are adapted to the seasonal availability of passage flows, with adults migrating upstream in December through March to spawn, and with juveniles migrating downstream in April through May to reach the ocean or tidal estuaries. To evaluate the effects of the proposed project on fish passage, flow exceedance curves were developed for the current condition and four project scenarios (see Appendix D). The four modeled scenarios are:

Case 1: Divert up to 2.99 cfs at Davis Road, leaving 2 cfs in-stream during the migration season (December-May), and 0.69 cfs in-stream during the other months (June-October). Divert up to 2.99 cfs at Castroville, leaving 1 cfs in-stream year-round.

Case 2: Divert up to 6 cfs at Davis Road, leaving 2 cfs in-stream during the migration season (December-May), and 0.69 cfs in-stream during the other months (June-October). Divert up to 2.99 cfs at Castroville, leaving 1 cfs in-stream year-round.

Case 3: Divert up to 2.99 cfs at Davis Road, leaving 1 cfs in-stream year-round. Divert up to 2.99 cfs at Castroville, leaving 1 cfs in-stream year-round.

Case 4: Divert up to 6 cfs at Davis Road, leaving 1 cfs in-stream year-round. Divert up to 2.99 cfs at Castroville, leaving 1 cfs in-stream year-round.

A qualified fisheries biologist identified several locations along the Reclamation Ditch and Tembladero Slough that present obstacles to fish passage[12]. Based upon his estimation of the flow rate needed to submerge the obstacle and allow the depth of flow needed for passage, the biologist may then use the flow exceedance curves to determine if the project will significantly affect the number of days the passage flows occur. Those results are reported separately in the Technical Memorandum by Hagar Environmental Science.

The obstacles identified were man-made erosion controls within the Reclamation Ditch, including stone rip-rap downstream of bridge crossings and the concrete weir and apron at the USGS stream gage. No obstacles to fish passage were identified in the Tembladero Slough, which has several feet of water depth even during dry seasons. The most restrictive location was the gaging weir at San Jon Road. If the proposed project diversions are found to have significant effects on fish passage, the effects may be mitigated in several ways.

---

[11] Reclamation Ditch Watershed Assessment and Management Strategy, Part A: Watershed Assessment, 2004

[12] Hagar Environmental Science, 2015

First, the obstacles may be removed or modified. Stone riprap for erosion control may be replaced with smaller, grouted stone or cast-in-place concrete. The concrete apron below the gaging weir may be replaced with a concrete lined plunge pool or a center channel. This would not remove the weir itself as an obstacle, but it would allow migrating fish a path to approach the weir before jumping.

A second mitigation method would be to determine the flow rate required to allow fish passage, and not divert flows at Davis Road when the base flow in the channel would otherwise allow passage. For the San Jon Road location, Hagar Environmental Science estimated the passage flow for upstream migration of adults at 78 cfs, and the passage flow for downstream migration of juveniles at 31 cfs. During the adult migration months of December through February, diversions would not be made when the base flow in the channel is between 78 and 84 cfs. If the flow is greater than 84 cfs, diverting 6 cfs for the project would still leave at least 78 cfs in-stream. Similarly, during the smolt migration months of March through May, diversions would not be made when the base flow in the channel is between 31 and 39 cfs. Schaaf & Wheeler estimated the passage flows separately, with higher results: 90 cfs for downstream migration of smolts and 121 cfs for upstream migration of adults. Because of the varying channel geometry across the short run of the weir and apron, the depth of flow on the downstream apron should be field measured during a rain event and a depth to flow curve developed.

The estimated average diversions at Davis Road when applying these non-diversion windows are shown in Table 2-6. The baseline scenario used is a 6 cfs target diversion rate, with a winter seasonal by-pass of 2 cfs and a summer season bypass of 0.69 cfs. The original model with no diversion windows is included for comparison. Project yields are reduced by approximately 1%, with the differences occurring in the wet season months. The non-diversion windows at Davis Road did not increase the yield of the Tembladero Slough diversion at Castroville, which remained 1,134 AFY in all cases.

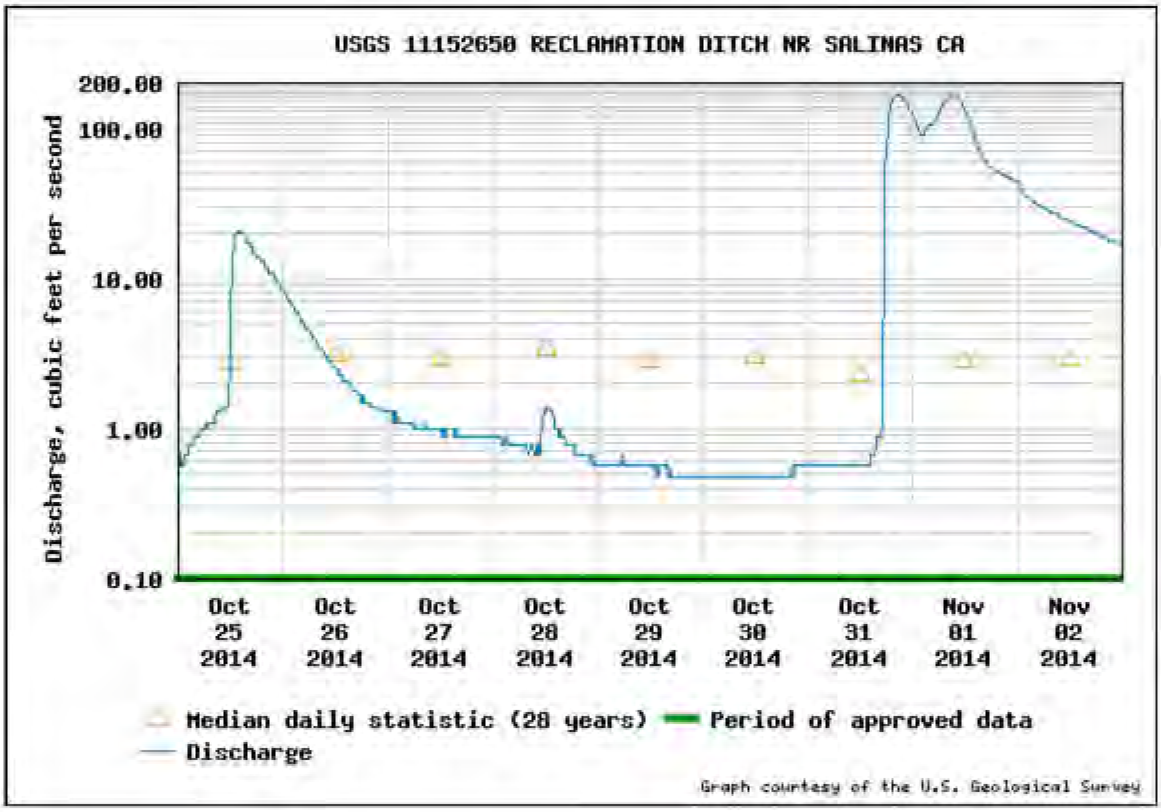
**Table 2-6: Estimated Davis Road Diversions with Mitigation Windows**

| Smolt | Adult | Jan | Feb | Mar | Apr | May | Jun | Jul | Aug | Sep | Oct | Nov | Dec | Total |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| 31 | 78 | 157 | 141 | 158 | 159 | 96 | 132 | 129 | 121 | 80 | 87 | 98 | 142 | 1,500 |
| 90 | 121 | 161 | 140 | 165 | 161 | 97 | 132 | 129 | 121 | 80 | 87 | 98 | 144 | 1,515 |
| 0 | 0 | 162 | 143 | 165 | 162 | 97 | 132 | 129 | 121 | 80 | 87 | 98 | 146 | 1,521 |

Smolt migration window March-May, Adult migration window December-February

The model uses mean daily streamflow data from the USGS gage at San Jon Road. Actual flow rates in the Reclamation Ditch rise and fall quickly following a rain event due the rapid inflow of runoff from the City of Salinas. Figure 2.5, below, shows the gaged flow following two rain events in 2014. On 10/25/2014, 0.2 inch of rainfall was recorded at Salinas Airport. The flow at San Jon Road peaked at 20 cfs, but the recorded average for the day was 7.5 cfs. On 10/31/2014, 1.0 inch of rainfall was recorded, with 0.4 inch recorded on the following day. The flow on 10/31/2014 peaked at 190 cfs, but the recorded average for that day was 37 cfs, and only 95 cfs for the following day. For comparison, the 2-year, 1-hour storm for Salinas is 0.4 inch, and the 2-year, 24-hour storm is 1.6 inches. What this shows is that more passage events occur during the year than the current modeling method can describe, and the corresponding non-diversion passage windows will occur more frequently as well.

**Figure 2.5: Discharge Curve at San Jon Road, 10/25/2014-11/02/2014**



## 2.3 Water Rights

Water that enters surface streams and rivers is considered water of the state. A water rights permit is required to impound or divert waters of the state, except for certain riparian uses. Diverting stormwater and agricultural return flows in the Reclamation Ditch and Tembladero Slough would be subject to water rights permitting rules. Existing surface water rights were researched to assess potential impacts to current water right holders or challenges to the proposed diversions.

The State Water Resources Control Board Electronic Water Rights Information Management System (eWRIMS) was queried to identify existing water rights in the Reclamation Ditch Watershed. A listing of all current water rights for Monterey County was obtained using a database query. The Points of Diversion (PODs) within the Reclamation Ditch watershed and vicinity were identified using the on-line GIS mapping tool. The POD listing was used to create a tailored list of water rights within the area of interest (see Table B-9).

**Figure 2.6: SWRCB eWRIMS Interface**

The SWRCB Water Rights Order 98-08, Declaration of Fully Appropriated Stream Systems in California, identifies those stream segments which cannot support additional authorizations for diversion. Neither the Reclamation Ditch nor the Lower Salinas River were listed in that decision, so there is no regulatory prohibition on requesting a water right on this stream.

The water rights listing includes several water right types:

- Appropriative, for the diversion and use of surface water.
- Stockpond, for the on-stream impoundment and use of water.

- Statements of Diversion and Use, for reporting riparian use of surface water and for the use of groundwater. Statements of Diversion and Use are also used for claims of pre-1914 appropriative water rights. The limitation of the eWRIMS database is that most Claimed water rights do not appear with a Face Amount the way Appropriative Rights are listed.

The listing incudes four large surface water rights on the Salinas River which are owned by MCWRA. The point of diversion at the SRDF (small blue square on the map above) was within the data capture for the list, and these rights were left in the table for information only.

The existing points of diversion within the Reclamation Ditch watershed below the City of Salinas are all for groundwater use. The sources for these are variously listed as "Salinas River Underflow," "Salinas Valley Basin," or "Groundwater." The shallow "A-Aquifer" groundwater in this area is not used due to poor water quality. Wells in this area tap the Pressure and East Side subareas of the Salinas Valley Groundwater Basin (SVGB), which is recharged in the Forebay and Upper Valley subareas. Diverting surface water for this project should not affect groundwater yields from the SVGB.

Above the City of Salinas, there are 16 surface water rights or claims listed, with face value diversion amounts totaling 2,155 AFY (see Table B-10). There are also 19 stock ponds listed of various sizes. All of these sites are above Old Stage Road within the Alisal, Gabilan and Natividad Creeks watersheds. The annual usage reports for 2011 and 2012 were reviewed, to the extent available. Reported use ranged from 3% to 71% of the total face value amount. The majority of these rights are limited to wet season diversions (NOV – APR), and will not affect summer channel flows. Because these rights are all located above the existing gage, the gaged flow values did not require adjustment. Likewise, the proposed diversion points for this project are well below the diversion points for these rights, so adding this project will not affect current surface water right holders.

# Section 3 - Facility Requirements

## 3.1 Description and Sizing

Conceptual designs were developed for diversion facilities at the two locations analyzed. The following design criteria and assumptions were used:

- The inlet would be located within the channel bottom
- The inlet will be screened to minimize fish and trash capture
- The pump station would consist of a wet well with submersible pumps
- The force main from the station will connect to a gravity portion of the existing sanitary sewer collection system (assumed discharge at atmospheric pressure)
- The minimum velocity in the force main shall be 2 feet/second to prevent the settling of suspended sediments in the pipeline.
- The maximum velocity in the force main shall be less than 8 feet/second to limit the friction losses

The conceptual design diagrams are provided in Appendix C.

The inlet structure consists of a concrete box with a screened inlet. The inlet must be sized to allow full flow through the screen with a maximum velocity of 1 ft/s to allow fish to escape. Assume the screen has an open area of 50%, and that 50% of the screen is blinded by trash/vegetation. For a maximum flow of 6 cfs:

$A_{screen}$ = 6 cfs / [(1 ft/s) x (50% screen openings) x (50% blinded)] = 24 sq-ft

Minimum dimensions: 4-ft wide x 6-ft long

The channel invert will be concrete lined with a permanent low-flow channel adjacent to the inlet. This will prevent capturing the required minimum by-pass flows. The channel banks above the inlet structure will be protected with grouted rip-rap to prevent scour and potential bank sloughing into the by-pass and inlet. Concrete steps should be installed above the inlet to facilitate maintenance access.

The inlet will connect to the wet well through a large diameter pipe, sloped towards the wet well. The wet well is an 8-ft diameter manhole, with mounting rails to facilitate the installation and removal of the submersible pumps. Within the wet well, the pumps will be set below the inlet pipe elevation. The pump operation will be controlled by a pressure transducer in the wet well, with float switches for backup control and alarms. Because the system will be discharging to the municipal sanitary sewer, pressure transducers or float switches must be installed in the receiving system to shut off this station when the receiving sewer is flowing full.

The force main to the sanitary sewer system should be C900 PVC pressure pipe, with a check valve and isolation valve located outside the wet well in a separate vault. The pipeline should be installed with a minimum of 3-ft of cover in the pipe trench. It will connect to the sanitary system at an existing manhole. If the existing sewer is deeper than the new force main, the force main should be installed with an interior drop (pipeline to the manhole invert) to minimize the turbulence and the release of $H_2S$ that it causes.

The pumps may operate at fixed speed or under variable speed control. Operation under fixed speed is simpler to design, but may require excessive cycling if the inflow rates are significantly lower than the pump design point. Variable speed control will allow the pumps to start and stop less frequently during the summer when flows are below 2 cfs.

For the Davis Road diversion point, two station configurations were considered. Option 1 assumed two pumps, primary and alternate, each sized to deliver 6 cfs through a shared force main. A 17 hp pump is required to provide 6 cfs of flow at that station. Option 2 assumed two independent pumps with separate force mains, each sized to deliver 3 cfs. An 8 hp pump is required to provide 3 cfs of flow. In either case, the station may be constructed next to the existing sanitary sewer main, minimizing the length of force main required. System Curves for the two configurations are provided in Figure 3.1 and Figure 3.2.

Looking at the statistics for flows at the USGS Gage at San Jon Road:

| | |
|---|---|
| Flows are less than 1 cfs: | 8% of the time |
| Flows are between 1 and 4 cfs: | 69% of the time |
| Flows exceed 5 cfs: | 23% of the time |

Given these operating conditions, we recommend installing 3 cfs pumps with parallel force mains. If redundancy is required, a third 3 cfs pump may be installed.

The Reclamation Ditch is designed to carry the 1% (100-year) storm event. The southern bank of the Reclamation Ditch where this pump station would be located is not shown as being within the 100-year flood-plain[13]. However, it would make sense to install the electrical equipment for this station on elevated panels.

The proposed station location is adjacent to the existing railroad right-of-way, as well as MCWRA's maintenance right-of-way. Due to these restrictions, it may not be possible to provide security fencing around the pump station and controls.

[13] FEMA Flood Insurance Rate Map, Map Panel 06053C0216G, April 2009 (see Appendix A)

**Figure 3.1: Davis Road Option 1, Two 6 cfs pumps**

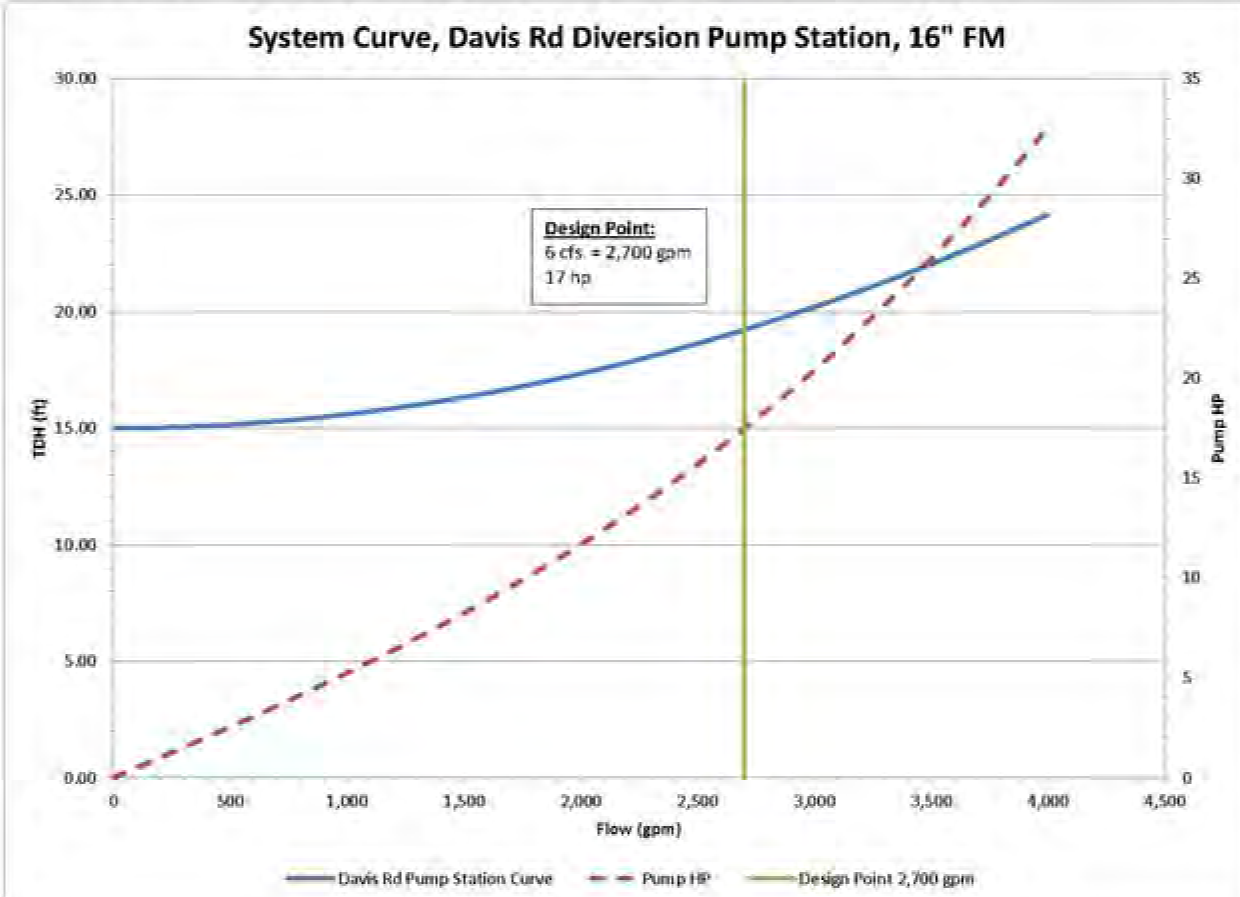


**Figure 3.2: Davis Road Option 2, Two 3 cfs pumps**

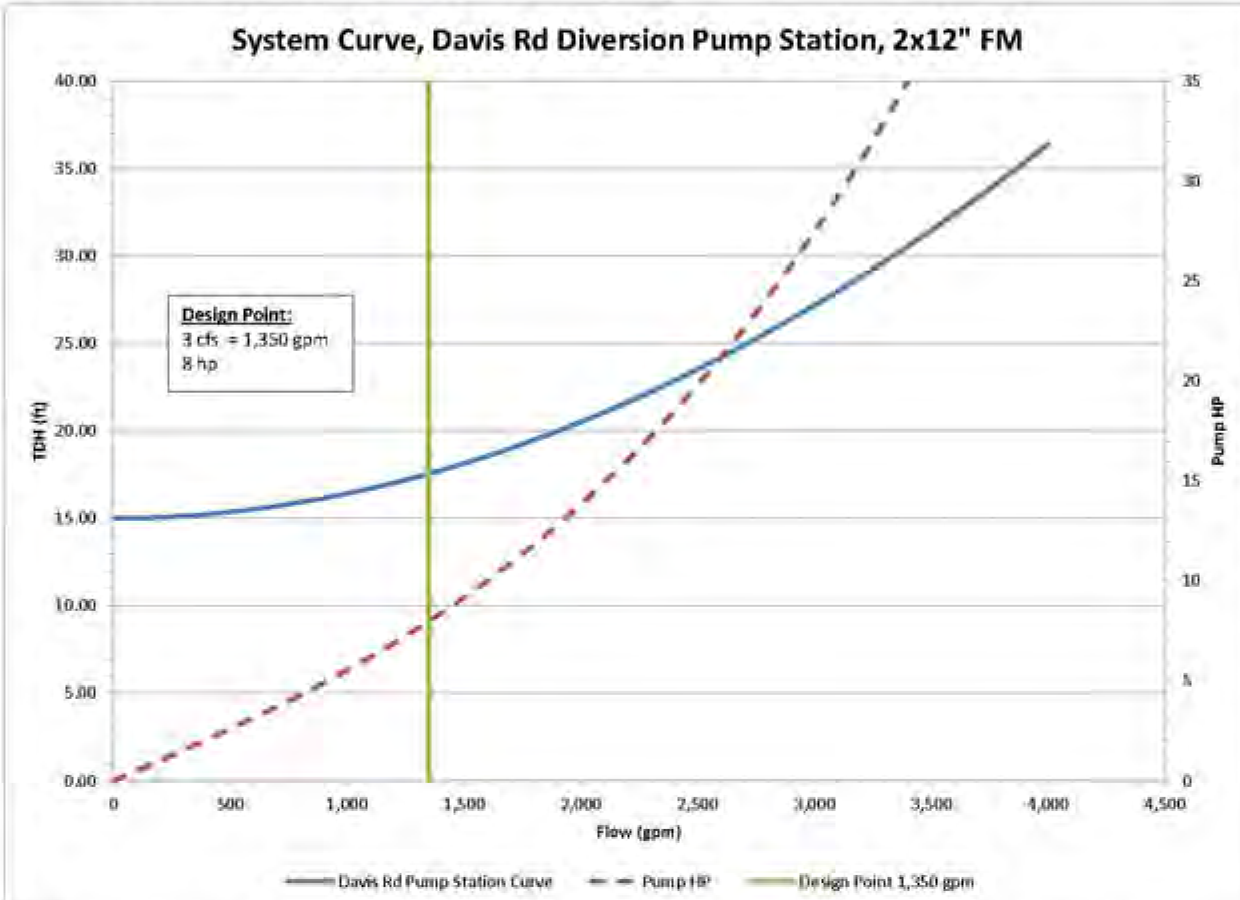
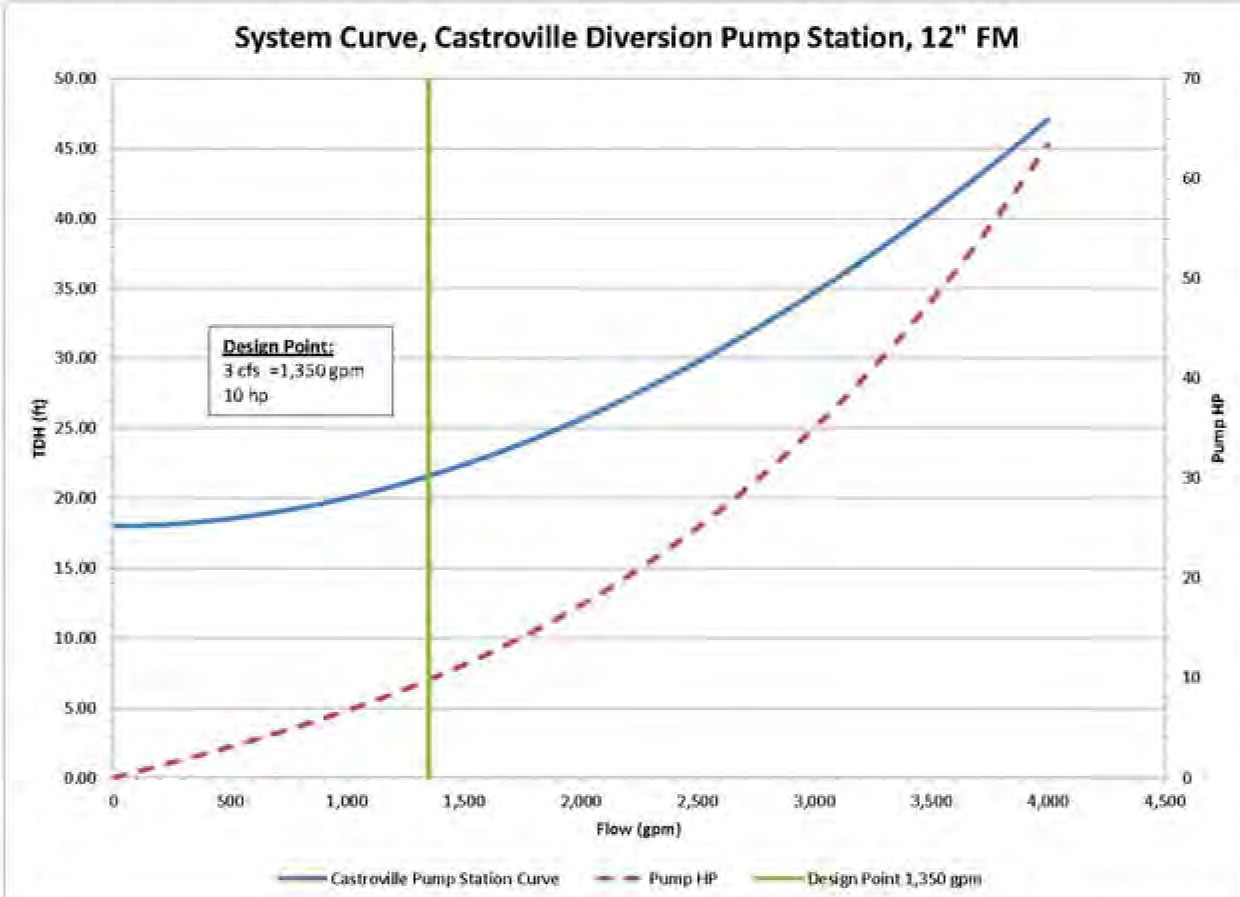


For the Castroville diversion point, the station will be similarly configured. The only difference is that the force main must be longer to reach the gravity manhole upstream of the MRWPCA Castroville Pump Station. A 10 hp pump is required to provide 3 cfs of flow at this station, due to the deeper wet well and longer force main. The system curve is provided at Figure 3.3.

The proposed station location is adjacent to MCWRA's maintenance right-of-way, in a lane also used for farm traffic. Due to the close proximity to the Castroville Pump Station, it may be possible to locate the electrical equipment at the existing building and avoid installing a free-standing panel. The site is within the 100-year floodplain, so the power and control equipment must be elevated above the base flood elevation of 13-ft[14].

[14] FEMA Flood Insurance Rate Map, Map Panel 06053C0070G, April 2009 (see Appendix A)

**Figure 3.3: Castroville Pump Station**



### 3.2 Costs

Capital costs were estimated for three pump station configurations, a 6 cfs station at Davis Road, a 3 cfs station at Davis Road, and a 3 cfs station at Castroville, summarized in Table 3-1, below. Detailed estimates are provided in Tables C-4, C-5 and C-6 in Appendix C. Non-construction costs (design, permitting, legal, etc.) were estimated as 40% of the construction cost.

Right-of-way acquisition costs were not included in the capital cost estimates. The proposed sites are within county or city rights-of-way, so standard encroachment fees should apply.

**Table 3-1: Estimated Capital Costs**

| | Davis Rd 6 cfs Pumps | Davis Rd 3 cfs Pumps | Castroville 3 cfs Pumps |
|---|---|---|---|
| Estimated Construction Cost | $352,000 | $346,000 | $331,000 |
| Inspection and Testing (15%) | $53,000 | $52,000 | $50,000 |
| Construction Contingency (20%) | $70,000 | $69,000 | $66,000 |
| Estimated Total Construction Cost | $475,000 | $467,000 | $447,000 |
| | | | |
| Design, Permitting, Legal (40%) | $190,000 | $186,800 | $178,800 |

Costs are in 1st Quarter 2014 dollars

The City of Salinas has standard capacity charges and monthly fees for connecting to the sanitary sewer collection system, which would apply to the Davis Road Pump Station. These fees are not included in this estimate, but should be considered if this option is pursued.

Similarly, the MRWPCA has standard capacity charges for connection to the regional wastewater system, based upon the flow rate, the biological oxygen demand (BOD) and the suspended solids concentration, and monthly charges for wastewater treatment. These fees are not included in this estimate, because the MRWPCA is a sponsor of the GWR Project. The primary, secondary and advanced treatment costs for this source of supply will appear in the overall project cost analysis.

Annual operating and debt service costs for each configuration were estimated using the following planning factors:

- Debt service assumes a 30-year bond at 4% annual interest
- Annual operation and maintenance of pump stations is estimated at 2.5% of the capital cost
- Annual operation and maintenance of pipelines is estimated at 1% of the capital cost
- Electrical power cost is assumed at $0.16 per kWh
- Assume the station operates 365 days a year

The factors above provide an order-of-magnitude estimate of annual costs, which may be used in comparing project configurations. The estimated annual costs are provided below.

**Table 3-2: Estimated Annual Costs, 6 cfs Pump Station at Davis Road**

| Category | Basis | Annual $ |
|---|---|---|
| **Capital Repayment** | | |
| Assume 30-year bond at 4% | $475,000.00 | $27,469.30 |
| **Annual Operation and Maintenance** | | |
| Assume 2.5% of Pump Station Capital Cost | $461,500.00 | $11,537.50 |
| Assume 1.0% of Pipeline Capital Cost | $13,500.00 | $337.50 |
| **Electrical Power** | | |
| Number of operating days/year | 336 | |
| Pumps: 17 HP (0.7457 kW/hp) | 12.7 | |
| Estimated annual kWh | 102,227 | |
| Assumed cost per KWH | $0.16 | $16,356.24 |
| **Total Estimated Annual Cost** | | **$55,700.00** |

**Table 3-3: Estimated Annual Costs, 3 cfs Pump Station at Davis Road**

| Category | Basis | Annual $ |
|---|---|---|
| **Capital Repayment** | | |
| Assume 30-year bond at 4% | $467,000.00 | $27,006.66 |
| **Annual Operation and Maintenance** | | |
| Assume 2.5% of Pump Station Capital Cost | $434,600.00 | $10,865.00 |
| Assume 1.0% of Pipeline Capital Cost | $32,400.00 | $810.00 |
| **Electrical Power** | | |
| Number of operating days/year | 336 | |
| Pumps: 8 HP (0.7457 kW/hp) | 6.0 | |
| Estimated annual kWh | 48,107 | |
| Assumed cost per KWH | $0.16 | $7,697.06 |
| **Total Estimated Annual Cost** | | **$46,400.00** |

**Table 3-4: Estimated Annual Costs, 3 cfs Pump Station at Castroville**

| Category | Basis | Annual $ |
|---|---|---|
| **Capital Repayment** | | |
| Assume 30-year bond at 4% | $447,000.00 | $25,850.05 |
| **Annual Operation and Maintenance** | | |
| Assume 2.5% of Pump Station Capital Cost | $422,700.00 | $10,567.50 |
| Assume 1.0% of Pipeline Capital Cost | $24,300.00 | $607.50 |
| **Electrical Power** | | |
| Number of operating days/year | 336 | |
| Pumps: 110 HP (0.7457 kW/hp) | 7.5 | |
| Estimated annual kWh | 60,133 | |
| Assumed cost per KWH | $0.16 | $9,621.32 |
| **Total Estimated Annual Cost** | | **$46,600.00** |

# Section 4 - Water Quality

## 4.1 Summary of Current Condition

The Central Coast Regional Water Quality Control Board (CCRWQCB) Water Quality Control Plan for the Central Coast Basin (Basin Plan) designated beneficial uses of the Reclamation Ditch as including water contact recreation, non-contact water recreation, wildlife habitat, warm water fish habitat and commercial or sport fishing. These are the minimum uses listed for all inland water bodies within the region, unless specific water quality information caused the RWQCB to remove a specific use (e.g., not listing water contact recreation for a stream segment listed for fecal coliform contamination). The Tembladero Slough is designated as having additional beneficial uses of estuarine habitat, rare/threatened/endangered species, and spawning/reproduction/early development habitat. Table B-11 in Appendix B lists the Basin Plan designations for all stream segments in the lower Salinas Valley.

CCRWQCB Order No. R3-2012-0011 (Conditional Waiver of Waste Discharge Requirements for Discharges from Irrigated Lands) found that:

> "...toxicity resulting from agricultural discharges of pesticides has severely impacted aquatic life in Central Coast streams...Twenty-two sites in the region, 13 of which are located in the lower Salinas/Tembladero watershed area, and the remainder in the lower Santa Maria area, have been toxic in 95% (215) of the 227 samples evaluated."

The Reclamation Ditch (Salinas Reclamation Canal) and Tembladero Slough are listed as impaired water bodies pursuant to Section 303(d) of the Clean Water Act for ammonia, fecal coliform, pesticides, nitrate, toxicity and other parameters. Water quality has been sampled and monitored for the past 15 years under various programs, including the Central Coast Ambient Monitoring Program (CCAMP) under the RWQCB, the Central Coast Watershed Studies (CCoWS) program of the Watershed Institute at California State University Monterey Bay, and the Cooperative Monitoring Program under the Conditional Waiver of Waste Discharges from Irrigated Lands (Ag Waiver). The results of these programs have been consolidated in Table B-12, Stream Water Quality, for the Reclamation Ditch, Tembladero Slough and all tributary water bodies. Figure A-9 shows the primary sampling locations.

The Reclamation Ditch and Tembladero Slough are not designated for use as municipal or domestic water supply, so Total Maximum Daily Loads (TMDL) for pollutants had to be established by the RWQCB. The Central Coast RWQCB adopted order R3-2013-0008 to establish certain TMDLs for the lower Salinas River Basin in 2013. These and other applicable water quality standards are consolidated in Table B-13, Total Maximum Daily Loads. A summary of the key parameters for the Reclamation Ditch are shown in Table 4-1, and for Tembladero Slough in Table 4-2.

**Table 4-1: Water Quality Parameters, Reclamation Ditch below Carr Lake**

| Parameter | Units | Mean | Max | Standard |
|---|---|---|---|---|
| Ammonia as N, Unionized | mg/L | 0.029 | 0.25 | 0.025 |

## 4.2 Potential Pollutant Removal

A benefit of the proposed GWR Project is that it can accept waters of marginal quality as source water because of the proposed routing through the sanitary sewer collection system to the MRWPCA Regional Treatment Plant and then to the existing tertiary treatment or the proposed advanced treatment system. Water diverted from the Reclamation Ditch and/or Tembladero Slough will remove a portion of the current pollutant load from the streams. The water quality within the streams may not noticeably improve, particularly in the summer months when the source flows are mainly agricultural tile drainage. The reduction in pollutant-loaded flows should have a positive effect on the water quality in the Moss Landing Harbor below Potrero Road tide gates.

Pollutant removal was estimated using the conversion formula 1 mg/L = 2.7 pounds/acre-foot. The tables below show the estimates for diverting 6 cfs at Davis Road, 3 cfs at Davis Road, and 3 cfs at Castroville. The current annual flow total is included for comparison.

**Table 4-3: Estimated Pollutant Removal at Davis Road, 6 cfs capacity**

| Pollutant | Average Conc. | Average Annual Flow | Average Pollutant Load | Diverted Flow | Diverted Pollutant Load |
|---|---|---|---|---|---|
| | (mg/L) | (AFY) | (lb/yr) | (AFY) | (lb/yr) |
| Ammonia as N, Unionized | 0.029 | 7,640 | 597 | 1,611 | 126 |
| Ammonia as NH3 | 0.61 | 7,640 | 12,581 | 1,611 | 2,653 |
| Chloride | 106.41 | 7,640 | 2,195,025 | 1,611 | 462,852 |
| Chlorophyll a, water column | 0.016 | 7,640 | 332 | 1,611 | 70 |
| Chlorpyrifos | 0.0016 | 7,640 | 32 | 1,611 | 7 |

## 4.3 Salinity in the Tembladero Slough

The Tembladero Slough and Old Salinas River channel are tidally influenced, with a well-defined halocline (higher salinity at the bottom of the channel[15]). The tidal effects are dampened by the tide (flap) gates on the Old Salinas River at Potrero Road, but brackish water still passes through the gates. The upstream migration of the saline layer is controlled, in part, by freshwater inflows that provide dilution at low flows and which push the salt water downstream at higher flows. The estuary typically sees seasonal increases in salinity, with peak levels occurring in late

[15] Central Coast Watershed Studies Program, 2010 and 2014 reports on Spatial and Temporal Variations on Streamflow and Water Quality in the Tembladero Slough

summer before the on-set of winter rains. Students in the Central Coast Watershed Studies Program at CSUMB studied salinity in the Tembladero Slough on several days in November 2010 and again in November 2014. Calendar year 2010 was a wet year, and also the first year that the Salinas River Diversion Facility (SRDF) was in operation. Releases from San Antonio and Nacimiento Reservoirs were increased for rediversion at the SRDF, and while the facility was operating a minimum of 2 cfs was released to the Salinas Lagoon, which is tributary to the Old Salinas River Channel. In 2010, the lagoon opened to the ocean on December 25 (after the 2010 sampling period was completed), and stayed open until September 21, 2011. Conversely, the 2014 sampling period came at the end of an extended drought, with record low rainfall during the period 2012-2014. The Salinas River Lagoon was last open to the ocean on January 27, 2013. The SRDF was not operated during the summer of 2014, so there were no upstream reservoir releases augmenting flows into the lagoon and the Old Salinas River.

The 2010 study found salinities at the lower end of the Tembladero Slough ranging from 1 to 15 parts per thousand (ppt). In 2014, salinities at that location ranged from 1 to 20 ppt. Seawater has salinity of about 35 ppt, so while there was a definite increase in salinity due to the prolonged drought, the Slough remained a brackish estuary. There were rainfall events during both the 2010 and 2014 sampling periods, and the post-rainfall sampling showed similar low salinities (under 1 ppt) in both years. The 2014 study extended the water sampling upstream into the Reclamation Ditch, and found that increased salinity extended as far upstream as Haro Road in Castroville, and that the halocline ended downstream of the town (salinity levels were uniform across the depth of the channel).

The Proposed Project will divert up to 80% of the available flows from the Reclamation Ditch/Tembladero Slough in the summer months (June to October), which may result in increased salinity near the water surface, and/or longer periods of salinity accumulation in the Tembladero Slough before seasonal flushing by winter runoff. Diversions from the Reclamation Ditch and Tembladero Slough would be most needed by the Project during dry years when irrigation demands are highest. Due to the tidal influence, water levels in the Slough would not be noticeably affected by the project, so wetland species would not see a loss of wetted habitat, only an increase in the duration of periods of higher salinity.

## Section 5 - Hydrology Considerations

The California Environmental Quality Act (CEQA) requires that effects of the Proposed Project on surface water hydrology be analyzed to identify impacts in the following areas:

a. Would the project substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, in a manner that would result in substantial erosion or siltation on- or off-site?

The diversion of flows from the Reclamation Ditch and Tembladero Slough may reduce the amount of sediment carried into the Old Salinas River and Moss Landing Harbor, but this reduction will be small. When diverting summer flows, the channel velocities and suspended sediment loads are low. Erosion and sediment transport occur during peak flows during and after rainfall events. These diversions may not be required to operate during wet winter months when storm runoff typically occurs. In that case, the conveyance of sediment from the Reclamation Ditch/Tembladero Slough into the Old Salinas River will be no greater than under the current condition.

The channel around the inlet structure for the diversion pump station would be lined with concrete to prevent local scour and erosion. The construction of the diversion structures and pipelines will require open-cut excavation, which will require the use of erosion and sediment controls to prevent the migration of sediments into the river. The Castroville diversion structure may require a temporary cofferdam to facilitate construction of the inlet structure.

b. Would the project substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or substantially increase the rate or amount of surface runoff in a manner that would result in flooding on- or off-site?

The proposed project components would increase impervious areas by a small amount (less than 1000 square feet each) at the Davis Road and Castroville sites. The Project would not substantially alter the existing drainage patterns of any of the proposed project sites.

c. Would the project create or contribute runoff water which would exceed the capacity of existing or planned stormwater drainage systems or provide substantial additional sources of polluted runoff?

The Project would add pump stations along the Reclamation Ditch at Davis Road and along the Tembladero Slough in Castroville. Up to 1,000 sq-ft of impervious surface may be added at each site, and runoff from the new hardscape would be directed to the existing drainage channels. The soils at these sites are Type C (runoff coefficient >80), so the increase in runoff will be small and within the available existing drainage system conveyance capacity. No impact is expected under this criterion.

d. Would the project place within a 100-year flood hazard area structures that would impede or redirect flood flows?

The proposed diversion pump stations at Davis Road and Castroville will include inlet structures in the channel bottom. These inlets must include a screen to exclude fish and trash, and must be configured to not alter the conveyance capacity of the Reclamation Ditch / Tembladero Slough.

Structures on the channel bank would be located within a 100-year flood hazard area, but will not impede or reduce flood flows because they are relatively small (less than 100 square feet) and would be located at sites that currently contain other above-ground structures of much larger size and profile, most notably the roadway bridge abutments immediately upstream.

## Definitions of FEMA Flood Zones

Flood zones are geographic areas that FEMA has defined according to varying levels of flood risk and type of flooding. These zones are depicted on the published Flood Insurance Rate Map (FIRM) or Flood Hazard Boundary Map (FHBM).

## Special Flood Hazard Areas – High Risk

Special Flood Hazard Areas represent the area subject to inundation by 1-percent-annual chance flood. Structures located within the SFHA have a 26-percent chance of flooding during the life of a standard 30-year mortgage. Federal floodplain management regulations and mandatory flood insurance purchase requirements apply in these zones.

| ZONE | DESCRIPTION |
|---|---|
| A | Areas subject to inundation by the 1-percent-annual-chance flood event. Because detailed hydraulic analyses have not been performed, no Base Flood Elevations (BFEs) or flood depths are shown. |
| AE, A1-A30 | Areas subject to inundation by the 1-percent-annual-chance flood event determined by detailed methods. BFEs are shown within these zones. (Zone AE is used on new and revised maps in place of Zones A1–A30.) |
| AH | Areas subject to inundation by 1-percent-annual-chance shallow flooding (usually areas of ponding) where average depths are 1–3 feet. BFEs derived from detailed hydraulic analyses are shown in this zone. |
| AO | Areas subject to inundation by 1-percent-annual-chance shallow flooding (usually sheet flow on sloping terrain) where average depths are 1–3 feet. Average flood depths derived from detailed hydraulic analyses are shown within this zone. |
| AR | Areas that result from the decertification of a previously accredited flood protection system that is determined to be in the process of being restored to provide base flood protection. |
| A99 | Areas subject to inundation by the 1-percent-annual-chance flood event, but which will ultimately be protected upon completion of an under-construction Federal flood protection system. These are areas of special flood hazard where enough progress has been made on the construction of a protection system, such as dikes, dams, and levees, to consider it complete for insurance rating purposes. Zone A99 may be used only when the flood protection system has reached specified statutory progress toward completion. No BFEs or flood depths are shown. |

Figure A-8 (Continued)

## Coastal High Hazard Areas – High Risk

Coastal High Hazard Areas (CHHA) represent the area subject to inundation by 1-percent-annual chance flood, extending from offshore to the inland limit of a primary front al dune along an open coast and any other area subject to high velocity wave action from storms or seismic sources. Structures located within the CHHA have a 26-percent chance of flooding during the life of a standard 30-year mortgage. Federal floodplain management regulations and mandatory purchase requirements apply in these zones.

| ZONE | DESCRIPTION |
|---|---|
| V | Areas along coasts subject to inundation by the 1-percent-annual-chance flood event with additional hazards associated with storm-induced waves. Because detailed coastal analyses have not been performed, no BFEs or flood depths are shown. |
| VE, V1-V30 | Areas along coasts subject to inundation by the 1-percent-annual-chance flood event with additional hazards due to storm-induced velocity wave action. BFEs derived from detailed hydraulic coastal analyses are shown within these zones. (Zone VE is used on new and revised maps in place of Zones V1–V30.) |

## Moderate and Minimal Risk Areas

Areas of moderate or minimal hazard are studied based upon the principal source of flood in the area. However, buildings in these zones could be flooded by severe, concentrated rainfall coupled with inadequate local drainage systems. Local stormwater drainage systems are not normally considered in a community's flood insurance study. The failure of a local drainage system can create areas of high flood risk within these zones. Flood insurance is available in participating communities, but is not required by regulation in these zones. Nearly 25-percent of all flood claims filed are for structures located within these zones.

| ZONE | DESCRIPTION |
|---|---|
| B, X (shaded) | Moderate risk areas within the 0.2-percent-annual-chance floodplain, areas of 1-percent-annual-chance flooding where average depths are less than 1 foot, areas of 1-percent-annual-chance flooding where the contributing drainage area is less than 1 square mile, and areas protected from the 1-percent-annual-chance flood by a levee. No BFEs or base flood depths are shown within these zones. (Zone X (shaded) is used on new and revised maps in place of Zone B.) |
| C, X (unshaded) | Minimal risk areas outside the 1-percent and .2-percent-annual-chance floodplains. No BFEs or base flood depths are shown within these zones. (Zone X (unshaded) is used on new and revised maps in place of Zone C.) |

## Undetermined Risk Areas

| ZONE | DESCRIPTION |
|---|---|
| D | Unstudied areas where flood hazards are undetermined, but flooding is possible. No mandatory flood insurance purchase requirements apply, but coverage is available in participating communities. |

Notes:
Assumed 1 cfs must be bypassed for environmental flows. 0.7 cfs bypass shown for comparison
Available PDWF capacity in Salinas gravity sewer estimated at 6 cfs. Assumes limiting pipe segment slope at 0.0003.
Does not account for future growth in Salinas. Per 2004 Salinas WWMP, this pipeline will approach full capacity at build-out.
Minimum flow in Reclamation Ditch occurs in September. Summer months carry irrigation return flows.

**Table B-5, Average Monthly Yields, Tembladero Slough at Castroville**

| Tembladero Slough at Castroville | | | | | | | | | | | | | |

Flows from USGS Gage 11152650, Reclamation Ditch at San Jon Road
Scaled to basin size at Davis Road (93.7%)
Assumes diversion structure will include low-flow bypass channel to prevent captureing 100% of daily flow.

Preliminary Design Cost Estimate

31-Mar-14
By: Josh Tabije

| Item of Work | Unit | Unit Cost | Quantity | Subtotal |
|---|---|---|---|---|
| ***Mobilization / Demobilization*** | | | | |
| ~ 5% of of project cost. This cost includes permits, fees, temporary structures, equipment rental and various misc. items | | | | ***$17,000*** |
| ***Clearing and Demolition*** | | | | |
| Demolition of Existing Facilities | LS | $10,000 | 1 | $10,000 |
| (By Department of Water Resources) | | | | ***$10,000*** |
| ***Structures*** | | | | |
| 96" Precast Manhole | EA | $30,000 | 1 | $30,000 |
| Cast-In-Place Concrete | CY | $1,000 | 40 | $40,000 |
| Concrete Dowel Inserts | EA | $300 | 30 | $9,000 |
| Wetwell Inlet Pipe | LF | $300 | 80 | $24,000 |
| | | | | ***$79,000*** |
| ***Miscellaneous Exterior Site Work*** | | | | |
| Excavation | CY | $140 | 180 | $25,200 |
| Site Shoring | SF | $3 | 1200 | $3,600 |
| Concrete Channel Lining | CY | $410 | 20 | $8,200 |
| Concrete Seal Slab | CY | $340 | 4 | $1,360 |
| Concrete Stairs | CY | $420 | 4 | $1,680 |
| Grouted RipRap | CY | $160 | 38 | $6,080 |
| | | | | ***$46,120*** |
| ***Pump Station/Channel Ammenities*** | | | | |
| 17 hp Pump | EA | $34,000 | 2 | $68,000 |
| Pump Installation | LS | $12,000 | 1 | $12,000 |
| Pump Discharge Pipe | LF | $200 | 50 | $10,000 |
| Aluminum Pump Access Hatch | EA | $17,900 | 1 | $17,900 |
| Fiberglass Railing | LS | $12,000 | 1 | $12,000 |
| | | | | ***$119,900*** |
| ***Site Piping*** | | | | |
| 16-Inch C900 PVC with Trench and Backfill | LF | $100 | 100 | $10,000 |
| | | | | ***$10,000*** |
| ***Electrical Equipment*** | | | | |
| Electrical Equipment (Including Installation) | LS | $60,000 | 1 | $60,000 |
| Electrical Conduit Run | LF | $100 | 100 | $10,000 |
| | | | | ***$70,000*** |
| **ESTIMATED CONSTRUCTION COST** | | | | **$352,020** |
| **INSPECTION AND TESTING (15%)** | | | | **$53,000** |
| **CONSTRUCTION CONTINGENCY (20%)** | | | | **$70,000** |
| **ESTIMATED TOTAL CONSTRUCTION COST** | | | | **$475,000** |

**This estimate of construction cost is a professional opinion, based upon the engineer's experience with the design and construction of similar projects. It is prepared only as a guide and is subject to change. Schaaf & Wheeler and its subconsultants make no warranty, whether expressed or implied, that the actual costs will not vary from these estimated costs, and assumes no liability for such variances. This estimate specifically excludes any costs associated with designing for handling and disposal of hazardous wastes and contaminated materials. Costs associated with land, right-of-way, or easement purchase are not included in this estimate.**

**Appendix D: Analysis Statistical Outputs**

Reclamation Ditch at Davis Road, Percentile Flows by Month
Tembladero Slough at Castroville, Percentile Flows by Month

**Scenario Notes:**

**Reclamation Ditch at Davis Road**

| | |
|---|---|
| **Case 0:** | Base Condition: Flow = USGS San Jon Road gage (11152650),<br>scaled down by a factor of 0.937 for Davis Rd. location |
| **Case 1:** | Divert up to 2.99 cfs of available flow from Reclamation Ditch at Davis Rd;<br>Leave a minimum base flow of 2 cfs Dec-May, or 0.69 cfs Jun-Nov |
| **Case 2:** | Divert up to 6.0 cfs of available flow from Reclamation Ditch at Davis Rd;<br>Leave a minimum base flow of 2 cfs Dec-May, or 0.69 cfs Jun-Nov |
| **Case 3:** | Divert up to 2.99 cfs of available flow from Reclamation Ditch at Davis Rd;<br>Leave a minimum base flow of 1.0 cfs year-round. |
| **Case 4:** | Divert up to 6 cfs of available flow from Reclamation Ditch at Davis Rd;<br>Leave a minimum base flow of 1.0 cfs year-round. |

**Tembladero Slough at Castroville**

| | |
|---|---|
| **Case 0:** | Base Condition: Flow = USGS San Jon Road gage (11152650),<br>scaled up by a factor of 1.4 for Castroville location |
| **Case 1:** | Divert up to 2.99 cfs of available flow from Reclamation Ditch at Davis Rd and<br>up to 2.99 cfs of available flow from Tembladero Slough at Catroville;<br>Leave minimum base flows of 2 cfs Dec-May, or 0.69 cfs Jun-Nov, in Reclamation Ditch;<br>Leave constant minimum base flow of 1 cfs in Tembladero Slough. |
| **Case 2:** | Divert up to 6.0 cfs of available flow from Reclamation Ditch at Davis Rd and<br>up to 2.99 cfs of available flow from Tembladero Slough at Catroville;<br>Leave minimum base flows of 2 cfs Dec-May, or 0.69 cfs Jun-Nov<br>Leave constant minimum base flow of 1 cfs in Tembladero Slough. |
| **Case 3:** | Divert up to 2.99 cfs of available flow from Reclamation Ditch at Davis Rd and<br>up to 2.99 cfs of available flow from Tembladero Slough at Catroville;<br>Leave minimum base flows of 1.0 cfs year-round in both Tembladero Slough and Rec Ditch. |
| **Case 4:** | Divert up to 6.0 cfs of available flow from Reclamation Ditch at Davis Rd and<br>up to 2.99 cfs of available flow from Tembladero Slough at Catroville;<br>Leave minimum base flows of 1.0 cfs year-round in both Tembladero Slough and Rec Ditch. |
| **Percentile Results:** | The flow with the nth percentile rank.<br>The 1.0 percetile flow is the highest daily flow.<br>The 0.50 percentile flow is the median daily flow.<br>The 0.01 percentile flow is exceeded 99% of the time (blank if 0.0 cfs). |

**Reclamation Ditch at Davis Rd, Annual Percentile Flows (cfs)**

| Annual Percentile | Case 0: | Case 1: | Case 2: | Case 3: | Case 4: |
|---|---|---|---|---|---|
| 1.00 | 252.99 | 250.00 | 246.99 | 250.00 | 246.99 |

## Summary of Blanco Drain Yield Study

The Monterey Peninsula Water Management District (MPWMD) and the Monterey Regional Water Pollution Control Agency (MRWPCA) are jointly sponsoring the proposed Pure Water Monterey Groundwater Replenishment Project (Proposed Project), a water supply project that will serve northern Monterey County. The project will provide purified water for recharge of the Seaside Groundwater Basin that serves as drinking water supply, and recycled water to augment the existing Castroville Seawater Intrusion Project agricultural irrigation supply. One of the proposed sources of water supply to be developed for this project is tile drainage and stormwater runoff from the Blanco Drain, which currently contributes flow to the Salinas River. The purpose of this study was to (1) analyze water availability in the Blanco Drain, (2) provide an engineering analysis of the potential yields and the infrastructure required to capture and convey those flows to the Proposed Project, and (3) assess the potential project impacts on hydrology and water quality.

The Blanco Drain watershed is approximately 6400 acres of agricultural land near the City of Salinas. Summer flows are predominantly agricultural tile drainage. Irrigation supply in this area is a mix of Salinas Valley Groundwater, recycled water from the Castroville Seawater Intrusion Project and surface water from the Salinas River Diversion Facility. Winter flows also include storm water runoff.

Yields were estimated just above the confluence of the Blanco Drain with the Salinas River. There is an existing pump station at that location used to lift flows from the Blanco Drain into the river during the Salinas River Diversion Facility operating season. To convey the flows to the MRWPCA Regional Treatment Plant, a new pipeline will be required from the proposed pump station, crossing under the Salinas River. Based on previous reviews of the Blanco Drain water quality by the regulatory agencies, it was assumed that all flows may be diverted for the GWR Project. The estimated annual yields for the Blanco Drain are:

2,050 ac-ft/yr, using a maximum diversion rate of 2.9 cfs

2,104 ac-ft/yr, using a maximum diversion rate of 2.99 cfs

2,620 ac-ft/yr, using a maximum diversion rate of 6 cfs

# Section 1 - Introduction

## 1.1 Project Description

The Monterey Peninsula Water Management District (MPWMD) and the Monterey Regional Water Pollution Control Agency (MRWPCA) are jointly sponsoring the proposed Pure Water Monterey Groundwater Replenishment Project (Proposed Project), a water supply project that will serve northern Monterey County. The project will provide purified water for recharge of the Seaside Groundwater Basin that serves as drinking water supply, and recycled water to augment the existing Castroville Seawater Intrusion Project agricultural irrigation supply.

Source water for the project would include agricultural wash water from the City of Salinas Industrial Wastewater Collection System, stormwater from MRWPCA member cities, secondary-treated effluent from the MRWPCA Regional Treatment Plant, and surface water diverted from the Reclamation Ditch, Tembladero Slough and Blanco Drain. Water supplied to the Proposed Project would undergo primary and secondary treatment at the existing Regional Treatment Plant. The portion used for groundwater recharge would then undergo advanced treatment at a new facility to be located at the MRWPCA site, and then be conveyed to the Seaside Groundwater Basin for injection. The portion used for agricultural irrigation would undergo tertiary treatment at the existing Salinas Valley Reclamation Plant, and distribution through the Castroville Seawater Intrusion Project system.

The MRWPCA provides wastewater treatment for municipalities along the Monterey Bay from Pacific Grove north to Moss Landing, and inland to the City of Salinas. Wastewater is collected in an interceptor pipeline system and conveyed to the Regional Treatment Plant (RTP), located two miles north of the City of Marina. A large portion of this incoming flow undergoes tertiary treatment and is used for unrestricted agricultural irrigation within the Castroville Seawater Intrusion Project system in the northern Salinas Valley. Flow that is not sent to the tertiary treatment system is discharged through an outfall to Monterey Bay after receiving secondary treatment. The RTP has an average dry weather design capacity of 29.6 million gallons per day (mgd) and a peak wet weather design capacity of 75.6 mgd. It currently receives and treats approximately 17 to 18 mgd of average dry weather flow and therefore has capacity to treat additional flows. The interceptor pipeline system also has currently unused or excess conveyance capacity. Most of the new source waters would be conveyed to the RTP using the existing wastewater collection system; water from Blanco Drain would be conveyed in a new pipeline directly to the RTP.

Transfers of source water flowing in known and definite channels, such as the Blanco Drain, to the GWR project and thence out of the Salinas Valley to the Monterey Peninsula would be a consumptive use that may require an appropriative permit from the State Water Resources Control Board (SWRCB). The purpose of this study was to analyze water availability in the Blanco Drain and provide an engineering analysis of the potential yields and the infrastructure required to capture and convey those flows to the RTP. This hydrologic information and analysis may then be used in a permit application to the SWRCB.

## 1.2 Water Source Description

The Blanco Drain is a man-made reclamation ditch draining approximately 6,400 acres of agricultural lands near Salinas, CA. The watershed is between the Salinas River and Alisal Slough, and discharges to the Salinas River at river mile 5 (see Figure A-1). The system is maintained by the Monterey County Water Resources Agency (MCWRA).

The system consists of three separate ditches (A, B, and C) as shown in Figure 1.1. Ditch A is what is commonly referred to as the Blanco Drain. A headwall and flap gate at the lower end of Ditch A prevents seasonal high flows in the Salinas River from migrating up the Blanco Drain channel (Figure 1.2). Until 2010, MCWRA operated a seasonal pump station at the confluence of ditches A, B and C to lift summer flows over a low weir and into the ditch channel. This was required to improve tile drainage into ditches B and C (Figure 1.3). The pump station was not operated in the winter months, and ditches B and C were allowed to fill and overflow the weir.

**Figure 1.1: Blanco Drain Schematic**

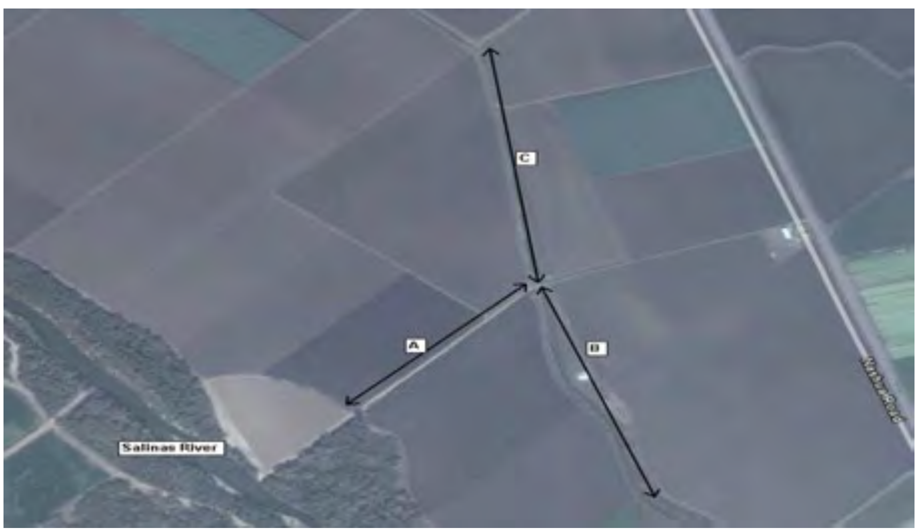

**Figure 1.2: Blanco Drain Flap Gate**

**Figure 1.3: Old Pump Station**

In 2009-2010, the MCWRA Salinas River Diversion Facility (SRDF) was constructed downstream of the Blanco Drain. The SRDF includes an inflatable rubber dam that impounds water during the summer months to supply the diversion pump station. To overcome the backwater into the Blanco Drain channel, the Blanco Drain channels were regraded and a new pump station was installed at the lower end of Ditch A. The new pump station (Figure 1.4) lifts Blanco Drain flows past a new slide gate and into the gravity portion of the channel.

**Figure 1.4: Current Pump Station**

Summer flows in the Blanco Drain are generally tile drainage and runoff from irrigated agriculture. Winter flows include stormwater runoff, although some fields remain in production and under irrigation year-round. Irrigation supply is predominantly groundwater from the Pressure Subarea of the Salinas Valley Groundwater Basin (see Figure A-2). A portion of the area tributary to the Blanco Drain is within the Castroville Seawater Intrusion Project (CSIP) service area (see figure A-3). The CSIP supplies growers with Recycled Water from the Salinas Valley Reclamation Plant (SVRP), located next to the MRWPCA RTP, and Salinas River water diverted at the MCWRA Salinas River Diversion Facility (SRDF).

During the summer months, the Salinas River flows into the Old Salinas River Channel through a gated culvert at the Salinas Lagoon. Direct discharge to the ocean is blocked by a seasonal sand bar which forms across the mouth of the Salinas Lagoon due to wave and tidal action in the Monterey Bay. The Old Salinas River channel is controlled by tide gates at Potrero Road in Moss Landing. River flow combines with Tembladero Slough flow approximately 1.2-miles above the tide gates. During high winter flows in the Salinas River, the sand bar breaches and the river flows directly to the Bay. When this occurs, MCWRA closes the slide gate to the Old Salinas River.

The Central Coast Regional Water Quality Control Board (CCRWQCB) has listed Blanco Drain on the impaired water body listing pursuant to Section 303(d) of the Clean Water Act for pesticides, nitrate and low dissolved oxygen. The lower Salinas River is also listed as an impaired water body for pesticides, nitrate, chloride and other parameters. A summary matrix of

303(d) listed streams is provided in Appendix B, Table B-1. Water quality is discussed in greater detail in Section 4 of this report.

Aquatic habitats within the Blanco Drain system are poor. In addition to the poor water quality, the system is generally maintained as a drainage canal without tree canopy. The adjacent agricultural lands are used for growing table crops (leafy greens, berries and artichokes). The growers prevent vegetation from establishing along the Ditch banks to discourage birds and rodents from nesting near their fields. The Biological Opinion for the Salinas Valley Water project, NMFS noted: “The outlet culvert of the Blanco Drain, where the drain enters the Salinas River, has a flap gate on its downstream end, preventing fish passage in Blanco Drain. Even if the flap gate fails and some fish are able to enter the drain, current water quality conditions are such that survival is not likely.[1]”

[1] NMFS, Biological Opinion for the Salinas River Diversion Facility, pg 84.

# Section 2 - Yield Estimation

## 2.1 Methodology

Estimates of stream flow capture from the Blanco Drain system were made, assuming diversion would occur at the existing MCWRA Blanco Drain pump station. Limited seasonal flow data was available for this location and was used as the basis of this analysis. The Blanco Drain is an 8-mile long channel that drains approximately 6,000 acres of irrigated agricultural land west of Salinas, CA. The terrain is generally flat with type C and D clay soils. Flows are primarily agricultural tile drainage.

The Blanco Drain connects to the Salinas River through a 60-inch pipe culvert with a flap gate. To facilitate drainage, MCWRA historically operated a pump station approximately 2-miles upstream of the pipe culvert, from the drain channel (parallel to the Salinas River) to the connecting channel. This pump station was replaced as part of the Salinas River Diversion Facility (SRDF) project. The current pump station is located at the upstream end of the 60-inch pipe culvert, and includes a slide gate which is closed when the SRDF rubber dam is inflated, and a by-pass pump station which lifts Blanco Drain flows past the gate structure.

Limited flow data is available for the Blanco Drain. A weir gage was installed in 2007 to record flows used in sizing the current pump station, and operational records for the pump station were obtained for 2010 through 2013 and used in this analysis. Because the SRDF only operates during the peak irrigation season (April to October), flow data was not recorded for the rest of the year.

Approximately one third of the area tributary to the Blanco Drain is within the Castroville Seawater Intrusion Project (CSIP) service area. The MCWRA publishes monthly records of the total CSIP water deliveries, which can be used to estimate applied irrigation per acre (= total deliveries ÷ 12,000 acre service area). Similar crops and irrigation methods are used throughout the Blanco Drain tributary areas, so it was assumed that the CSIP irrigation rates applied to the full area.

Flows from the Blanco Drain were estimated as return flows from applied irrigation and natural precipitation. For the months with recorded Blanco Drain flow data, the source flows were calculated as:

(CSIP Irrigation) + (Precipitation at Salinas) x 6,000 acres = total acre-feet/month

Return Rate = (Blanco Drain Flow) / (total ac-ft/mo)

The calculated return rates ranged from 3% to 25%, with an average return of 16.8% (see Table B-2: Blanco Drain Flows as Return Flows). The period with the most complete flow data for the Blanco Drain was August to October 2013, with an average return rate of 16.9%. For this estimate, we assumed a flat 17% return rate. The MCWRA CSIP records were combined with the Salinas rainfall records to calculate the total estimated source flows (Table B-4: Applied Irrigation and Recorded Precipitation in the CSIP Service Area). The return flows were estimated by month as shown below.

**Table 2-1: Estimated Return Flows into Blanco Drain**

| Month | Applied Irrig + Precip | 17% return | Avg Return Flow Rate |
|---|---|---|---|
| | AF | AF | cfs |
| January | 1,229 | 209 | 3.4 |
| February | 1,314 | 223 | 4.0 |
| March | 1,446 | 246 | 4.0 |
| April | 1,481 | 252 | 4.2 |
| May | 1,323 | 225 | 3.7 |
| June | 1,613 | 274 | 4.6 |
| July | 1,629 | 277 | 4.5 |
| August | 1,436 | 244 | 4.0 |
| September | 1,080 | 184 | 3.1 |
| October | 989 | 168 | 2.7 |
| November | 782 | 133 | 2.2 |
| December | 1,088 | 185 | 3.0 |
| **Totals** | **15,410** | **2,620** | |

The values shown in Table 2-1 are monthly average values. Although the average monthly return flow rates range from 2.2 to 4.6 cfs, daily flows rates over 6 cfs have been recorded during the four years the Blanco Drain pump station has been in operation. To achieve an annual average diversion of 2,620 AFY, a peak diversion rate of 6 cfs is therefore required. Yields applying lower average station capacities are shown in Table 2-2. If excess flows on peak days may be stored in-channel behind the slide gate and held until the following day, diverting at a lower rate may be feasible. However, the current pump station configuration and operating regimen is designed to drain the channel to facilitate tile drainage, so the use of in-channel storage should not be assumed.

**Table 2-2: Estimated Yields based on Pump Capacity**

| Station Capacity | Yield |
|---|---|
| cfs | AFY |
| 2.9 | 2,050 |
| 2.99 | 2,104 |
| 3.0 | 2,110 |
| 3.5 | 2,350 |
| 4.0 | 2,538 |
| 4.5 | 2,613 |
| 4.6 | 2,619 |

The permitting process for a water right diversion rate less than 3 cfs is shorter than for a larger diversion rate, so the proposed project assumes an initial water right diversion at 2.99 cfs, and an ultimate water right allowing diversions at up to 6 cfs. Both capacities are considered in Section 3, Facility Requirements.

## 2.2 In-Stream Flow Requirements

For this report, we assumed that all flows within the Blanco Drain are available for diversion and capture. This is based upon previous documentation in the Salinas Valley Water Project EIR and the supporting Biological Opinion prepared by NMFS for the SRDF construction. Those documents identify (1) the water quality within the Blanco Drain is poor and does not support aquatic species, (2) the flap gate between the river and the Blanco Drain prevents the migration of fish from the river into the drain, and (3) the water quality at the downstream Salinas Lagoon would be improved if the flows from the Blanco Drain were diverted to the MRWPCA Regional Treatment Plant.

As a condition of operating the SRDF, MCWRA must maintain certain in-stream flows in the Salinas River. When San Antonio and Nacimiento Reservoirs have a combined storage of 220,000 acre-feet, the SRDF has a requirement to release (1) a minimum of 15 cfs downstream from April 1 to June 30, and (2) a minimum of 2 cfs downstream from July 1 to the end of the SRDF operating season for maintenance of the Salinas River Lagoon habitat. Higher block flow releases are triggered during steelhead migration season if the Salinas Lagoon is open to the ocean. When the combined storage in the two reservoirs is under 220,000 ac-ft, the minimum release requirement for Lagoon habitat maintenance is 2 cfs while the SRDF is in operation. In Table 2-3, we compare the recorded daily by-passed flows at the SRDF (fish ladder plus regulating weir, as shown in Figure 2.1) to the recorded Blanco Drain flows during year 2012. Additional flow is reported to have spilled over the rubber dam during this period, but that volume was not estimated. MCWRA manages releases to by-pass the required minimum plus the Blanco Drain flow[2], so this proposed diversion should not impact SRDF operation.

**Table 2-3: SRDF By-Passed Flows, with and without Blanco Drain[3]**

| Month | Year | Avg Daily By-Passed Flow | Blanco Drain Flow | Average minus B.D. | Required Minimum By-Pass |
|---|---|---|---|---|---|
| | | cfs | cfs | cfs | cfs |
| 4 | 2012 | 22.5 | 4.7 | 17.8 | 2.0 |
| 5 | 2012 | 18.6 | 5.2 | 13.4 | 2.0 |
| 6 | 2012 | 9.1 | 5.4 | 3.7 | 2.0 |
| 7 | 2012 | 10.1 | 5.2 | 4.9 | 2.0 |

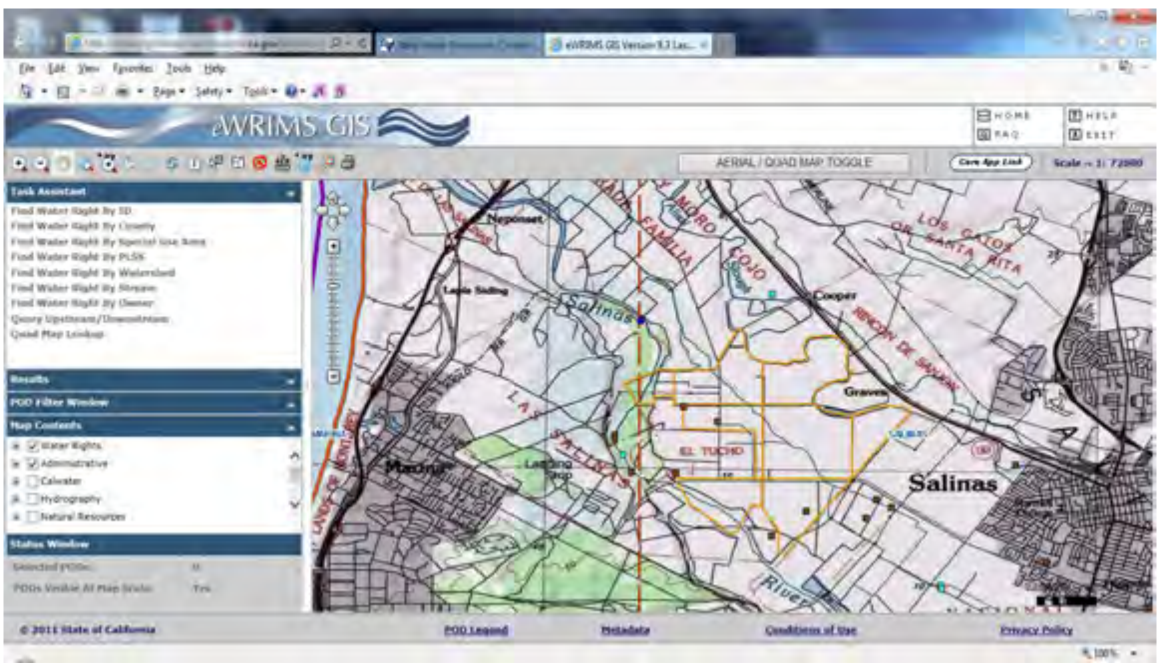
**Figure 2.1: SRDF Release Weir**

## 2.3 Water Rights

Water that enters surface streams and rivers is considered water of the state. A water rights permit is required to impound or divert waters of the state, except for certain riparian uses. Stormwater and agricultural return flows in the Blanco Drain would be subject to water rights permitting rules. Existing surface water rights were researched to assess potential impacts to current water right holders or challenges to the proposed diversions.

The State Water Resources Control Board Electronic Water Rights Information Management System (eWRIMS) was queried to identify existing water rights in the Lower Salinas Watershed. A listing of all current water rights for Monterey County was obtained using a database query. The Points of Diversion (PODs) within the Lower Salinas watershed and vicinity were identified using the on-line GIS mapping tool. The POD listing was used to create a tailored list of water rights within the area of interest (see Table B-4).

**Figure 2.2: SWRCB eWRIMS Interface**



The SWRCB Water Rights Order 98-08, Declaration of Fully Appropriated Stream Systems in California, identifies those stream segments which cannot support additional authorizations for diversion. Neither the Blanco Drain nor the Lower Salinas River were listed in that decision, so there is no regulatory prohibition on requesting a water right on this stream.

The water rights listing includes several water right types:

- Appropriative, for the diversion and use of surface water.
- Stockpond, for the on-stream impoundment and use of water.

- Statements of Diversion and Use, for reporting riparian use of surface water and for the use of groundwater. Statements of Diversion and Use are also used for claims of pre-1914 appropriative water rights. The limitation of the eWRIMS database is that most Claimed water rights do not appear with a Face Amount the way Appropriative Rights are listed.

There are no surface water rights or claims listed within the Blanco Drain watershed. The existing points of diversion within the Blanco Drain watershed are all for groundwater use. The sources for these are listed as “Salinas River Underflow.” The shallow “A-Aquifer” groundwater in this area is not used due to poor water quality. Wells in this area tap the Pressure subarea of the Salinas Valley Groundwater Basin (SVGB), which is recharged in the Forebay and Upper Valley subareas. Diverting surface water for this project should not affect groundwater yields from the SVGB.

The Blanco Drain is tributary to the Salinas River, just above the SRDF (small blue square on the map above). The MCWRA has three water rights (Permits 10137, 21089 and 12261) for water diversion and storage in San Antonio and Nacimiento Reservoirs, with authorized points of rediversion at the SRDF (see Table B-5). There are no surface water rights with points of diversion below the SRDF. MCWRA has a fourth water right, Permit 11043, for run-of-river flows with two authorized points of diversion upstream of the Blanco Drain. This fourth water right has not been used but has a priority date of July 11, 1949.

# Section 3 - Facility Requirements

## 3.1 Description and Sizing

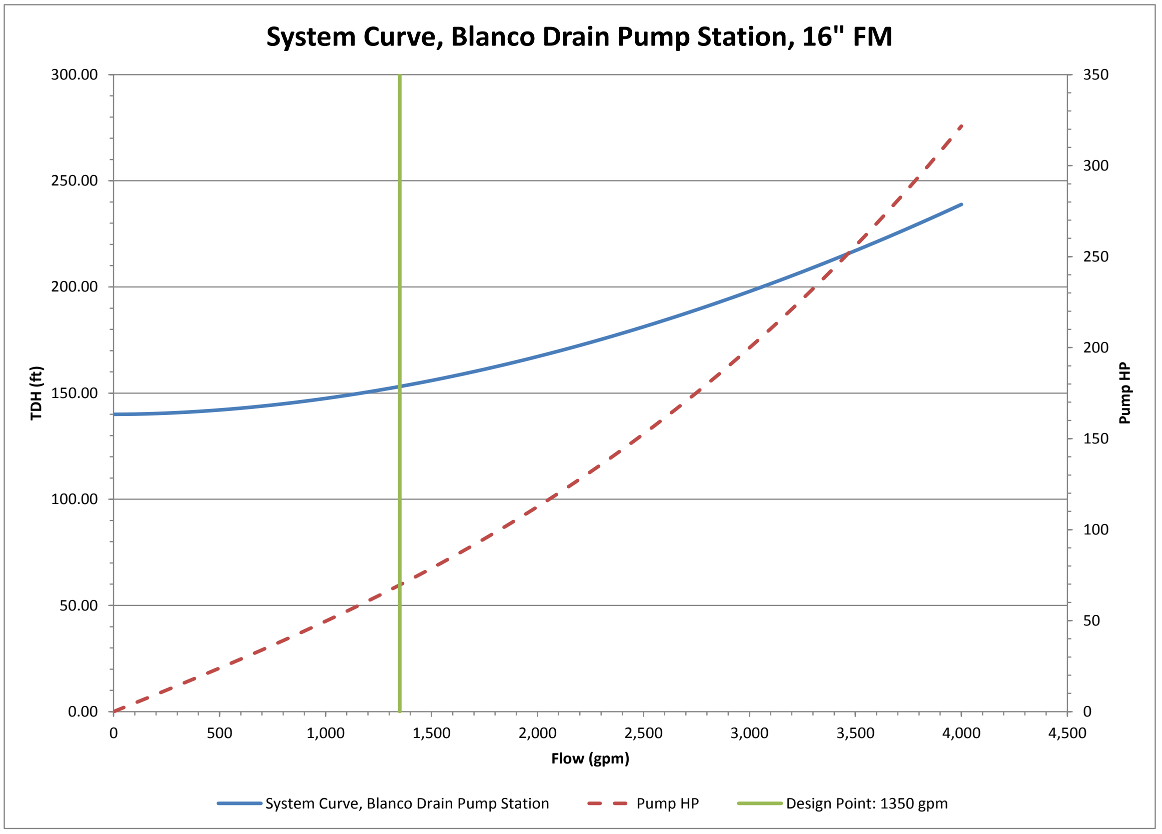
As stated in the Project Description, water supplies for the GWR Project will be conveyed to the RTP using existing excess capacity in the MRWPCA interceptor system. There are no interceptor facilities near the Blanco Drain, so a new pipeline will be required to convey flows to the RTP. There is an existing diversion pump station on the Blanco Drain, used to lift flows from the Drain to the Salinas River while the SRDF rubber dam is inflated. The station consists of a concrete weir with a slide gate, a concrete-box intake structure in the channel bottom, a concrete manhole to house the pumps, a concrete deck above the manhole for the electrical panel and concrete stairs for maintenance operation. As can be seen in the photo below, the current station has a small static lift and a free discharge just below the weir. The plan and profile design drawings are included as Figures C-1 and C-2 in Appendix C.

**Figure 3.1: Existing Blanco Drain Pump Station**

A similar pump station would be required to divert flows for the GWR project. Significantly larger pumps will be needed due to the increased static lift and force main length. The proposed force main is approximately 9,500 LF, from the existing pump station to the head-works side of the RTP (see Figure C-3). A static lift of 140-ft is estimated from the Blanco Drain to the highest point along the force main alignment.

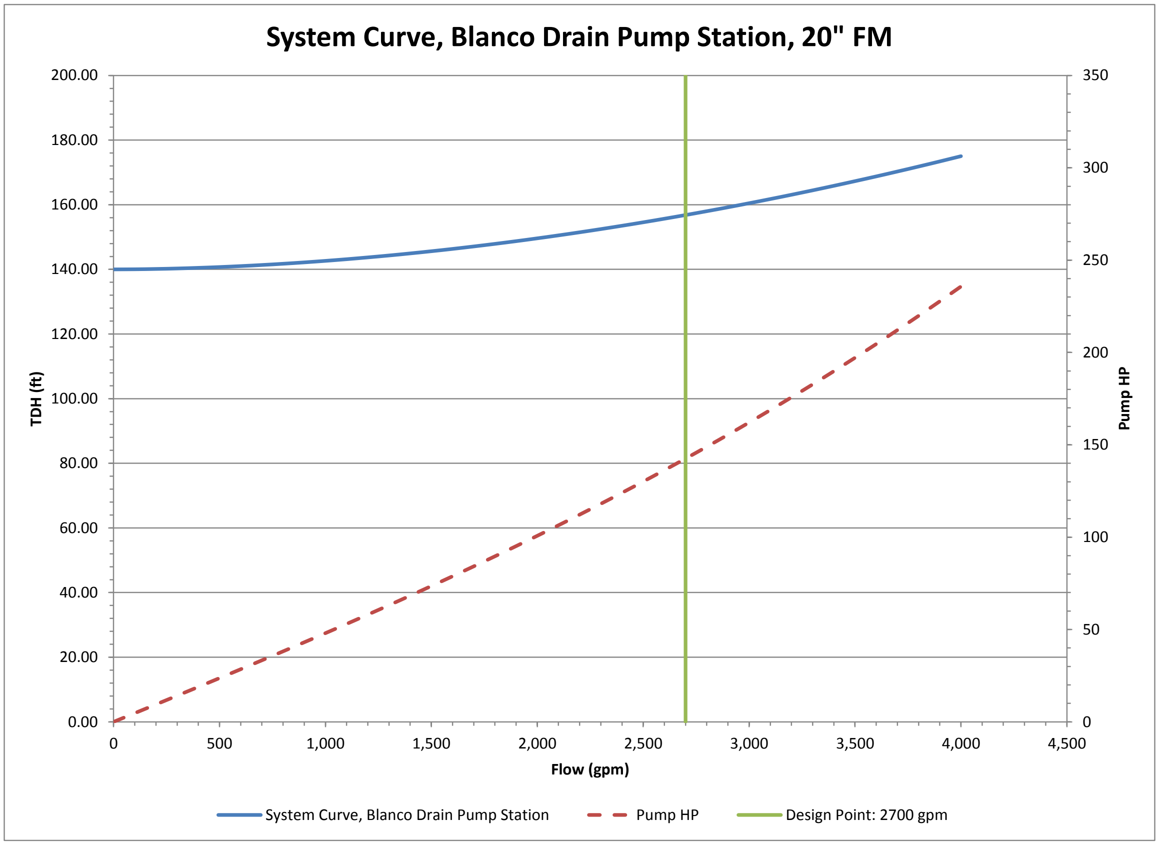
Several flow rates and force main sizes were considered. The force main should be sized for a minimum velocity of 2 ft/s to prevent solids from settling out in the pipeline, and a maximum velocity of 8 ft/s to limit the friction losses. For a 2.99 cfs diversion (nominally 1350 gpm), an 88 hp pump and a 16-in force main are required (see Figure 3.2). For the peak flow rate of 6 cfs (nominally 2700 gpm), a 143 hp pump and a 20-inch force main are required (see Figure 3.3). System head tables are provided in Appendix C.

**Figure 3.2: System Curve for a 16-inch Force Main**



It may be possible to modify the existing pump station to also serve the GWR Project, rather than construct a duplicate pump station next to the existing MCWRA facility. A new wet well may be constructed adjacent to and connected to the existing wet well. This would allow for shared use of the existing inlet structure and pipeline. A second option would be to construct a "mirror" station on the opposite bank, sharing only the inlet box. Either option would use the existing pump station to move excess Blanco Drain flows that exceed the GWR Project diversions into the Salinas River. Conceptual site plan diagrams are provided as Figures C-4 and C-5 in Appendix C.

**Figure 3.3: System Curve for a 20-inch Force Main**



The inlet structure consists of a concrete box with a screened inlet. The inlet must be sized to allow full flow through the screen with a maximum velocity of 1 ft/s to allow fish to escape. Assume the screen has an open area of 50%, and that 50% of the screen is blinded by trash/vegetation. For a maximum flow of 6 cfs:

$A_{screen}$ = 6 cfs / [(1 ft/s) x (50% screen openings) x (50% blinded)] = 24 sq-ft

Minimum dimensions: 4-ft wide x 6-ft long

The existing inlet box is 8-ft x 8-ft, so it exceeds the required minimum.

The channel invert surrounding the intake should be concrete lined to prevent scour during high flow periods. Similarly, the channel banks above the inlet structure should be protected with grouted rip-rap to prevent scour and potential bank sloughing into the inlet. As can be seen in Figure 3.1, the channel bank at the existing pump station is experiencing some erosion within the first year of operation.

The inlet will connect to the wet well through a large diameter pipe, sloped towards the wet well. A new wet well may be connected to the northwest side of the existing wet well (opposite the inlet pipe). The new wet well would be an 8-ft diameter manhole, with mounting rails to facilitate the installation and removal of the submersible pumps. Within the wet well, the pumps will be set below the inlet pipe elevation. The pump operation may be controlled by a pressure transducer in the wet well, with float switches for backup control and alarms. Because the system will be discharging to the RTP head works, a SCADA radio connection to the MRWPCA controls system is recommended so that this station may be shut down to facilitate maintenance at the RTP.

The force main to the RTP must be pressure pipe (typically HDPE, PVC or ductile iron), with a check valve and isolation valve located outside the wet well in a separate vault. The pipeline should be installed with a minimum of 4-ft of cover in the pipe trench. The segment crossing the Salinas River must be installed using trenchless methods. Directional drilling is the most likely method, but the RWQCB may prescribe a different method for the river crossing. The CSIP supply pipeline crosses the river near the SRDF facility. This crossing should be made upstream of the SRDF to avoid potential conflicts.

The pumps may operate at fixed speed or under variable speed control. Operation under fixed speed is simpler to design, but may require excessive cycling if the inflow rates are significantly lower than the pump design point. Variable speed control will allow the pumps to start and stop less frequently.

The proposed pump station is located in a FEMA floodway (Salinas River Overbank). The proposed submersible pumps will not be affected by storm inundation, but the power and control equipment must be elevated above the base flood elevation of 27-ft[4].

The Blanco Drain is within a 40-ft wide parcel, owned by Monterey County. As can be seen on the existing facility drawing, that parcel does not reach to the top of the existing bank. An easement with the adjacent property owner was required for the existing pump station, and an additional easement must be obtained for a GWR pump station and force main.

Construction of the pump station will require regulatory permits from many agencies, including the Army Corps of Engineers (Clean Water Act, Section 404), the CC RWQCB (Clean Water Act, Section 401) and the California Department of Fish and Wildlife. The National Marine Fisheries Service may be required to prepare a Biological Opinion as well.

[4] FEMA Flood Insurance Rate Map, Map Panels 06053C0205G and 06053C0185G, April 2009 (see Appendix A)

### 3.2 Costs

Capital costs were estimated for two pump station configurations, a 3 cfs station with a 16-inch force main, and a 6 cfs station with a 20-inch force main, summarized in Table 3-1, below. The cost of constructing the force main from the pump station to the MRWPCA RTP is just over half of the total capital cost. Detailed estimates are provided in Tables C-3 and C-4 in Appendix C. Non-construction costs (design, permitting, legal, etc.) were estimated as 40% of the construction cost.

Right-of-way acquisition costs were not included in the capital cost estimates. Easements across private property must be negotiated with landowners. The affected agricultural lands are typically in active cultivation during the construction season, so a premium cost should be anticipated.

**Table 3-1: Estimated Capital Costs**

| | 3 cfs Pump Station | 6 cfs Pump Station |
|---|---|---|
| Estimated Construction Cost | $1,789,420 | $2,280,420 |
| Inspection and Testing (15%) | $268,000 | $342,000 |
| Construction Contingency (20%) | $358,000 | $456,000 |
| Estimated Total Construction Cost | $2,415,000 | $3,078,000 |
| | | |
| Design, Permitting, Legal (40%) | $966,000 | $1,232,000 |

Costs are in 1st Quarter 2014 dollars

The MRWPCA has standard capacity charges for connection to the regional wastewater system, based upon the flow rate, the biological oxygen demand (BOD) and the suspended solids concentration, and monthly charges for wastewater treatment. These fees are not included in this estimate, because the MRWPCA is a sponsor of the GWR Project. The primary, secondary and advanced treatment costs for this source of supply will appear in the overall project cost analysis.

Annual operating and debt service costs for each configuration were estimated using the following planning factors:

- Debt service assumes a 30-year bond at 4% annual interest
- Annual operation and maintenance of pump stations is estimated at 2.5% of the capital cost
- Annual operation and maintenance of pipelines is estimated at 1% of the capital cost
- Electrical power cost is assumed at $0.16 per kWh
- Assume the station operates 365 days a year

The factors above provide an order-of-magnitude estimate of annual costs, which may be used in comparing project configurations. The estimated annual costs are provided below.

**Table 3-2: Estimated Annual Costs, 3 cfs Pump Station**

| Category | Basis | Annual $ |
|---|---|---|
| **Capital Repayment** | | |
| Assume 30-year bond at 4% | $2,415,000.00 | $139,659.69 |
| **Annual Operation and Maintenance** | | |
| Assume 2.5% of Pump Station Capital Cost | $795,000.00 | $19,875.00 |
| Assume 1.0% of Pipeline Capital Cost | $1,620,000.00 | $40,500.00 |
| **Electrical Power** | | |
| Number of operating days/year | 365 | |
| Pumps: 88 HP (0.7457 kW/hp) | 65.6 | |
| Estimated annual kWh | 574,845 | |
| Assumed cost per KWH | $0.16 | $91,975.23 |
| **Total Estimated Annual Cost** | | **$292,000.00** |

**Table 3-3: Estimated Annual Costs, 6 cfs Pump Station**

| Category | Basis | Annual $ |
|---|---|---|
| **Capital Repayment** | | |
| Assume 30-year bond at 4% | $3,078,000.00 | $178,001.05 |
| **Annual Operation and Maintenance** | | |
| Assume 2.5% of Pump Station Capital Cost | $1,093,500.00 | $27,337.50 |
| Assume 1.0% of Pipeline Capital Cost | $1,984,500.00 | $49,612.50 |
| **Electrical Power** | | |
| Number of operating days/year | 365 | |
| Pumps: 143 HP (0.7457 kW/hp) | 106.6 | |
| Estimated annual kWh | 934,123 | |
| Assumed cost per KWH | $0.16 | $149,459.76 |
| **Total Estimated Annual Cost** | | **$404,400.00** |

# Section 4 - Water Quality

## 4.1 Summary of Current Condition

The Central Coast Regional Water Quality Control Board (CCRWQCB) Water Quality Control Plan for the Central Coast Basin (Basin Plan) designated beneficial uses of the Blanco Drain as including water contact recreation, non-contact water recreation, wildlife habitat, warm water fish habitat and commercial or sport fishing. These are the minimum uses listed for all inland water bodies within the region, unless specific water quality information caused the RWQCB to remove a specific use (e.g., not listing water contact recreation for a stream segment listed for fecal coliform contamination).

The Blanco Drain is listed as an impaired water body pursuant to Section 303(d) of the Clean Water Act for pesticides, nitrate and low dissolved oxygen. Water quality has been sampled and monitored for the past 15 years under various programs, including the Central Coast Ambient Monitoring Program (CCAMP) under the RWQCB, the Central Coast Watershed Studies (CCoWS) program of the Watershed Institute at California State University Monterey Bay, and the Cooperative Monitoring Program under the Conditional Waiver of Waste Discharges from Irrigated Lands (Ag Waiver). The results of these programs have been consolidated in Table B-6, Stream Water Quality, for the Blanco Drain and all downstream inland water bodies. Figure A-6 shows the primary sampling locations.

The Blanco Drain is not designated for use as municipal or domestic water supply, so Total Maximum Daily Loads (TMDL) for pollutants had to be established by the RWQCB. The Central Coast RWQCB adopted order R3-2013-0008 to establish certain TMDLs for the lower Salinas River Basin in 2013. These and other applicable water quality standards are consolidated in Table B-6, Total Maximum Daily Loads. A summary of the key parameters for the Blanco Drain are shown in Table 4-1, below.

**Table 4-1: Water Quality Parameters, Blanco Drain above Salinas River**

| Parameter | Units | Mean | Max | Standard |
|---|---|---|---|---|
| Ammonia as N, Unionized | mg/L | 0.014 | 0.26 | 0.025 |
| Ammonia as NH3 | mg/L | 0.20 | 4.96 | 0.025 |
| Chlorophyll a, water column | mg/L | 0.0021 | 0.028 | 0.015 |
| Chlorpyrifos | mg/L | 0.0009 | 0.018 | 0.00025 |
| Diazinon | mg/L | 0.01 | 0.17 | 0.00016 |
| Dissolved Solids, Total | mg/L | 2,019 | 2,250 | 1,000 |
| Nitrate as N | mg/L | 65.27 | 325.00 | 8.0 |
| OrthoPhosphate as P | mg/L | 0.85 | 4.40 | 0.3 |
| Oxygen, Dissolved | mg/L | 0.20 | 2.52 | > 5.0 |
| Turbidity | NTU | 66.48 | 1,210.00 | 10 |

### 4.2 Potential Pollutant Removal

In the Biological Opinion for the SRDF Project, NMFS recommended diverting the Blanco Drain flows to the RTP as a means of improving the habitat in the Salinas River Lagoon. Removing water from the drain will carry dissolved pollutants out of the environment along with the water. The quantity removed may be estimated using the conversion factor 1 mg/L = 2.7 lb/AF. The tables below show the estimated annual pollutant removal, assuming average annual flow conditions and historic average pollutant concentrations for two conditions: a 6 cfs pumping capacity and a 3 cfs pumping capacity.

**Table 4-2: Estimated Pollutant Removal at Blanco Drain, 6 cfs capacity**

| Pollutant | Average Conc. | Average Annual Flow | Average Pollutant Load | Diverted Flow | Diverted Pollutant Load |
|---|---|---|---|---|---|
| | (mg/L) | (AFY) | (lb/yr) | (AFY) | (lb/yr) |
| Ammonia as N, Unionized | 0.014 | 2,620 | 98 | 2,620 | 98 |
| Ammonia as NH3 | 0.20 | 2,620 | 1,432 | 2,620 | 1,432 |
| Chlorophyll a, water column | 0.0021 | 2,620 | 15 | 2,620 | 15 |
| Chlorpyrifos | 0.00085 | 2,620 | 6 | 2,620 | 6 |
| Diazinon | 0.011 | 2,620 | 76 | 2,620 | 76 |
| Dissolved Solids, Total | 2019.7 | 2,620 | 14,287,358 | 2,620 | 14,287,358 |
| Nitrate as N | 65.27 | 2,620 | 461,726 | 2,620 | 461,726 |
| OrthoPhosphate as P | 0.85 | 2,620 | 6,026 | 2,620 | 6,026 |

**Table 4-3: Estimated Pollutant Removal at Blanco Drain, 3 cfs capacity**

| Pollutant | Average Conc. | Average Annual Flow | Average Pollutant Load | Diverted Flow | Diverted Pollutant Load |
|---|---|---|---|---|---|
| | (mg/L) | (AFY) | (lb/yr) | (AFY) | (lb/yr) |
| Ammonia as N, Unionized | 0.014 | 2,620 | 98 | 2,110 | 79 |
| Ammonia as NH3 | 0.20 | 2,620 | 1,432 | 2,110 | 1,153 |
| Chlorophyll a, water column | 0.0021 | 2,620 | 15 | 2,110 | 12 |
| Chlorpyrifos | 0.00085 | 2,620 | 6 | 2,110 | 5 |
| Diazinon | 0.011 | 2,620 | 76 | 2,110 | 61 |
| Dissolved Solids, Total | 2019.7 | 2,620 | 14,287,358 | 2,110 | 11,506,231 |
| Nitrate as N | 65.27 | 2,620 | 461,726 | 2,110 | 371,848 |
| OrthoPhosphate as P | 0.85 | 2,620 | 6,026 | 2,110 | 4,853 |

# Section 5 - Hydrology Considerations

The California Environmental Quality Act (CEQA) requires that effects of the Proposed Project on surface water hydrology be analyzed to identify impacts in the following areas:

a. Would the project substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, in a manner that would result in substantial erosion or siltation on- or off-site?

The Blanco Drain diversion would capture some stormwater which currently flows to the Salinas River. Reducing runoff from the Blanco Drain would reduce the amount of sediment carried into the main stem of the Salinas River. The channel around the inlet structure for the diversion pump station would be lined with concrete to prevent local scour and erosion. The Blanco Drain diversion may not be required to operate during wet winter months when storm runoff typically occurs. In that case, the conveyance of sediment from the Blanco Drain into the River will be no greater than under the current condition.

The construction of the Blanco Drain diversion structure and pipeline will require open-cut excavation, which will require the use of erosion and sediment controls to prevent the migration of sediments into the river. The pipeline crossing of the river will be installed using trenchless methods to avoid impacts to the channel. The pipeline trench will be restored to prevent erosion, either by reseeding (if outside a roadway) or by resurfacing if in a trafficked area.

b. Would the project substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or substantially increase the rate or amount of surface runoff in a manner that would result in flooding on- or off-site?

The Project would not make physical changes to the Salinas River, and the changes at the Blanco Drain diversion will not alter the channel cross-section. The operation of the Project would reduce the amount of surface runoff entering the river. The proposed project components would increase impervious areas by less than 1000 square feet each at the diversion pump station. The Project would not substantially alter the existing drainage patterns of any of the proposed project sites of the area.

c. Would the project create or contribute runoff water which would exceed the capacity of existing or planned stormwater drainage systems or provide substantial additional sources of polluted runoff?

The Project would add a new pump station on the bank of the Blanco Drain. Up to 1,000 square-feet of impervious surface may be added, and runoff from the new hardscape would be directed to the existing drainage channel. The soils in this area is Type C (runoff coefficient >80), so the increase in runoff will be small and within the available existing drainage system conveyance capacity. No impact is expected under this criterion

d. Would the project place within a 100-year flood hazard area structures that would impede or redirect flood flows?

The Project would add a diversion pump station on the Blanco Drain adjacent to an existing pump station which would be located within a 100-year flood hazard area. The proposed Blanco Drain pump station intake would be located at the channel bottom, and would be configured to not alter the conveyance capacity of the Blanco Drain. The pump station would not impede or reduce flood flows because they are low profile, small (less than 500 square-feet of vertical structures) and would be located at sites that currently contain similar above-ground structures of similar size and profile.

## Definitions of FEMA Flood Zones

Flood zones are geographic areas that FEMA has defined according to varying levels of flood risk and type of flooding. These zones are depicted on the published Flood Insurance Rate Map (FIRM) or Flood Hazard Boundary Map (FHBM).

## Special Flood Hazard Areas – High Risk

Special Flood Hazard Areas represent the area subject to inundation by 1-percent-annual chance flood. Structures located within the SFHA have a 26-percent chance of flooding during the life of a standard 30-year mortgage. Federal floodplain management regulations and mandatory flood insurance purchase requirements apply in these zones.

| ZONE | DESCRIPTION |
|---|---|
| **A** | Areas subject to inundation by the 1-percent-annual-chance flood event. Because detailed hydraulic analyses have not been performed, no Base Flood Elevations (BFEs) or flood depths are shown. |
| **AE, A1-A30** | Areas subject to inundation by the 1-percent-annual-chance flood event determined by detailed methods. BFEs are shown within these zones. (Zone AE is used on new and revised maps in place of Zones A1–A30.) |
| **AH** | Areas subject to inundation by 1-percent-annual-chance shallow flooding (usually areas of ponding) where average depths are 1–3 feet. BFEs derived from detailed hydraulic analyses are shown in this zone. |
| **AO** | Areas subject to inundation by 1-percent-annual-chance shallow flooding (usually sheet flow on sloping terrain) where average depths are 1–3 feet. Average flood depths derived from detailed hydraulic analyses are shown within this zone. |
| **AR** | Areas that result from the decertification of a previously accredited flood protection system that is determined to be in the process of being restored to provide base flood protection. |
| **A99** | Areas subject to inundation by the 1-percent-annual-chance flood event, but which will ultimately be protected upon completion of an under-construction Federal flood protection system. These are areas of special flood hazard where enough progress has been made on the construction of a protection system, such as dikes, dams, and levees, to consider it complete for insurance rating purposes. Zone A99 may be used only when the flood protection system has reached specified statutory progress toward completion. No BFEs or flood depths are shown. |

Figure A-5 (continued)

## Coastal High Hazard Areas – High Risk

Coastal High Hazard Areas (CHHA) represent the area subject to inundation by 1-percent-annual chance flood, extending from offshore to the inland limit of a primary front al dune along an open coast and any other area subject to high velocity wave action from storms or seismic sources. Structures located within the CHHA have a 26-percent chance of flooding during the life of a standard 30-year mortgage. Federal floodplain management regulations and mandatory purchase requirements apply in these zones.

| ZONE | DESCRIPTION |
|---|---|
| **V** | Areas along coasts subject to inundation by the 1-percent-annual-chance flood event with additional hazards associated with storm-induced waves. Because detailed coastal analyses have not been performed, no BFEs or flood depths are shown. |
| **VE, V1-V30** | Areas along coasts subject to inundation by the 1-percent-annual-chance flood event with additional hazards due to storm-induced velocity wave action. BFEs derived from detailed hydraulic coastal analyses are shown within these zones. (Zone VE is used on new and revised maps in place of Zones V1–V30.) |

## Moderate and Minimal Risk Areas

Areas of moderate or minimal hazard are studied based upon the principal source of flood in the area. However, buildings in these zones could be flooded by severe, concentrated rainfall coupled with inadequate local drainage systems. Local stormwater drainage systems are not normally considered in a community's flood insurance study. The failure of a local drainage system can create areas of high flood risk within these zones. Flood insurance is available in participating communities, but is not required by regulation in these zones. Nearly 25-percent of all flood claims filed are for structures located within these zones.

| ZONE | DESCRIPTION |
|---|---|
| **B, X (shaded)** | Moderate risk areas within the 0.2-percent-annual-chance floodplain, areas of 1-percent-annual-chance flooding where average depths are less than 1 foot, areas of 1-percent-annual-chance flooding where the contributing drainage area is less than 1 square mile, and areas protected from the 1-percent-annual-chance flood by a levee. No BFEs or base flood depths are shown within these zones. (Zone X (shaded) is used on new and revised maps in place of Zone B.) |
| **C, X (unshaded)** | Minimal risk areas outside the 1-percent and .2-percent-annual-chance floodplains. No BFEs or base flood depths are shown within these zones. (Zone X (unshaded) is used on new and revised maps in place of Zone C.) |

## Undetermined Risk Areas

| ZONE | DESCRIPTION |
|---|---|
| **D** | Unstudied areas where flood hazards are undetermined, but flooding is possible. No mandatory flood insurance purchase requirements apply, but coverage is available in participating communities. |

| # | Site ID | Site Name |
|---|---|---|
| 1 | 306MOR | Moro Cojo Slough @ Highway 1 |

Notes:

CSIP/SRDF/SVRP data from MCWRA

CSIP Service area approx 12,000 acres

Blanco Drain area approx 6,000 acres

Rainfall measured at Salinas Airport gage

Measured flow from weir (2007) and Blanco Drain pump station (2010-2012)

April and October are omitted from summary (partial month data)

Recorded Blanco Drain Flows

| | AVG % | AVG Q |
|---|---|---|
| May | 23.5% | 247.5 |
| June | 16.1% | 266.9 |
| July | 16.2% | 264.7 |
| August | 20.1% | 289.5 |
| Sept. | 17.9% | 208.0 |

Statistics for all available data

| | AVG | MAX | MIN |
|---|---|---|---|
| Loss (AF) | 1182 | 1924 | 604 |
| Pct Return | 16.8% | 24.7% | 1.4% |

Revision note: Measured flows at Blanco Drain for year 2012 updated per May 2014 revision to "SVWP Annual Flow Monitoring Report WY2012"

## Table C-2: Blanco Drain Divserion Pump Station, 20-inch Force Main

### System Head Calculations

| Parameter | Value |
|---|---|
| Number of Pumps in Parallel | **1** |
| Pump Discharge Diameter (inches) | **14** |
| Length of Pump Discharge (feet) | **40** |
| Discharge Hazen-Williams Coefficient (C) | **130** |
| Force Main Diameter in PS#2 (inches) | **16** |
| Force Main Length in PS#2 (feet) | **0** |
| Force Main Diameter from PS#2 to MH (inches) | **20** |
| Force Main Length from PS#2 to MH (feet) | **9500** |
| Force Main Hazen-Williams Coefficient (C) | **120** |
| Outfall Elevation (feet) | **143.00** |
| Wetwell Pumping Level (feet) | **3.00** |
| Static Lift (feet) | 140.00 |

| Fitting | K Value |
|---|---|
| 45 Elbow | 0.2 |
| 90 Elbow | 0.3 |
| 22.5 Elbow | 0.075 |
| 11.25 Elbow | 0 |
| GV | 0.3 |
| CV | 2.5 |
| Reducer | 0.03 |
| FR Elbow | 0.3 |
| Tee branch | 0.75 |

| Pump Discharge Piping | | | | | | | | | | | | Force Main in PS | | | | | Force Main from PS to MH | | | | | | | | | |

## Summary of Lake El Estero Yield Study

The Monterey Peninsula Water Management District (MPWMD) and the Monterey Regional Water Pollution Control Agency (MRWPCA) are studying the proposed Groundwater Replenishment Project (Proposed Project), with the goal of producing highly treated recycled water supply for injection into the Seaside Groundwater Basin to replace existing supplies. The purpose of this study was to analyze the availability of stormwater runoff from portions of the City of Monterey for this project, and provide an engineering analysis of the infrastructure required and the effect of flow reductions to the Monterey Bay.

The City of Monterey maintains Lake El Estero as the central feature of the Lake El Estero Municipal Park. The Lake covers approximately 18-acres, and collects runoff from approximately 3.78 square-miles of urban, suburban and wooded area. Although the Lake is within one mile of the Monterey Bay, it does not directly connect to ocean. The Lake level is maintained for aesthetics and recreation use, and storm flows are pumped to the ocean through a gated pipeline. Two gravity pipelines provide an overflow outlet from the Lake to the beach.

Diverting stormwater flows into the sanitary sewer system as a source of supply for the Proposed Project was analyzed. Annual runoff into the Lake was estimated to average 268 acre-feet per year. Of that, an average of 87 acre-feet per year may be diverted to the Proposed Project using existing capacity in the City's wastewater collection system. Stormwater not captured for the Proposed Project would remain in the Lake or continue to be discharged to the ocean.

The drainage basin immediately to the west of the Lake drained into Lake El Estero until 1941, when a new storm sewer was installed in Figueroa Street which redirected those flows to Del Monte Beach. This basin is approximately 1.85 square-miles, and produces an estimated average runoff of 227 acre-feet per year. If this drainage basin were reconnected to the Lake, the average Proposed Project yield would increase to 136 acre-feet per year.

Limited water quality sampling indicates that the water in Lake El Estero is of a better quality than City stormwater discharging directly to the Bay. The Lake provides a basin for sediments and metals to settle out of the water column. As such, it is currently one of the more benign sources of fresh water inflow to the Bay. The Monterey Bay at Del Monte Beach is not classified as an estuary, so minimum targets for freshwater inflows have not been established. Reducing the annual discharge of stormwater is not anticipated to have a negative effect on the Bay water quality. If stormwater flows that currently discharge directly to the Bay are routed through the Lake, the average quality of stormwater discharges would be expected to improve. The only noted water quality risk of the Proposed Project is an increased chance of overflows in the sanitary sewer system due to adding stormwater to a portion of the collection system. Automated in-pipe flow monitoring will be required to shut off the stormwater diversion system if the pipeline capacity is needed to convey peak wet weather sanitary sewer flows.

# Section 1 - Introduction

## 1.1 Project Description

The Monterey Peninsula Water Management District (MPWMD) and the Monterey Regional Water Pollution Control Agency (MRWPCA) are studying the proposed Monterey Peninsula Groundwater Recharge Project (Proposed Project), with the goal of producing highly treated recycled water supply for injection into the Seaside Groundwater Basin. Source water for the project may come from the City of Salinas Industrial Wastewater Treatment Facility, the Reclamation Ditch, the Blanco Drain, stormwater from MRWPCA member cities and/or secondary effluent from the MRWPCA Regional Treatment Plant. Water supplied to the Proposed Project would undergo primary and secondary treatment at the existing Regional Treatment Plant, followed by advanced treatment at a new facility to be located at the MRWPCA site, and then be conveyed to the Seaside Groundwater Basin for injection.

The MRWPCA provides wastewater treatment for municipalities along the Monterey Bay from Pacific Grove north to Moss Landing, and inland to the City of Salinas. Wastewater is collected in an interceptor pipeline system and conveyed to the Regional Treatment Plant (RTP), located north of the City of Marina. The RTP has an average dry weather design capacity of 29.6 million gallons per day (mgd) and a peak wet weather design capacity of 75.6 mgd. It currently receives and treats approximately 17 to 18 mgd of average dry weather flow and therefore has capacity to treat additional flows. The interceptor pipeline system also has currently unused or excess conveyance capacity. The Proposed Project will use the existing excess capacity in the wastewater interceptor system to convey source flows to the RTP using, rather than constructing a parallel conveyance system.

The purpose of this study was to analyze water availability from urban stormwater runoff into Lake El Estero and provide an engineering analysis of the potential yields and the infrastructure required to capture and convey those flows to the RTP. Transfers of source water flowing in known and definite channels, such as the City of Monterey's Lake El Estero, to the Proposed Project would be a consumptive use that may require an appropriative permit from the State Water Resources Control Board (SWRCB). If a permit is required, this hydrologic information and analysis may be used in the permit application to the SWRCB.

## 1.2 Water Source Description

Lake El Estero is an 18-acre lake located in the City of Monterey, less than one mile from the coast. It is fed by four tributary streams and a portion of the City's stormwater collection system. One tributary is a named stream (Majors Creek which runs through Dahvee Park), and the other three are unnamed streams. The Lake El Estero drainage basin is 2,418 acres, or approximately 3.78 square miles.

The Lake was originally a brackish lagoon, connected by a surface stream to the Monterey Bay. The connection to the bay was changed to pipe culverts in the 1870s when the Monterey and Salinas Valley Railroad was constructed. The Lake has been dredged several times during the last century to remove accumulated sediment. Until 1941, the drainage basin included 1,186-acres to the west, extending to Huckleberry Hill, which entered the Lake through a box culvert under Pearl Street. This portion of the City stormwater system was reconfigured with the addition of a box culvert under Figueroa Street, which now carries the flow from Pearl Street to discharge into the Monterey Bay at the Municipal Wharf. In 1968, the current stormwater pump station at the northeast corner of the lake and outfall pipeline were constructed to facilitate better management of water levels in the Lake.

In 1999, Fugro West[1] prepared a study of potential non-potable water supplies for the City of Monterey, and concluded that shallow groundwater percolates into Lake El Estero. Based upon their observations, groundwater inflows were estimated at 135 acre-feet/year. These inflows were found to replace evaporative losses and provide irrigation supply water to the City, which uses lake water for irrigation of the surrounding park (and cemetery). This groundwater inflow was not considered for diversion to the Proposed Project.

The Lake is surrounded by the City of Monterey's El Estero Park Complex, which includes sports facilities, play grounds, a fishing pier and a paddle boat wharf. The lake provides habitat for fish, amphibians, reptiles and native and migratory birds.

The Central Coast Regional Water Quality Control Board (CCRWQCB) has listed Majors Creek on the impaired water body listing pursuant to Section 303(d) of the Clean Water Act for copper, lead, zinc and Escherichia coli concentrations, and has listed the Monterey Harbor as impaired for metals and sediment toxicity. Lake El Estero is not a listed water body. A summary matrix of 303(d) listed streams is provided in Table B-1. Water quality is discussed in greater detail in Section 4 of this report.

[1] Engineering Analysis, Development of Non-Potable Irrigation Water Systems, pages 24-25

# Section 2 - Yield Estimation

## 2.1 Methodology

Estimates of surface runoff into Lake El Estero from the City of Monterey were made based on daily rainfall gage data, National Resource Conservation Service[2] mapped hydrologic soil group information, and land use as shown on aerial photographs. Calculations were made for each day and aggregated by month and water year (October 1 through September 30) using the methods in SCS Manual TR-55, Urban Hydrology for Small Watersheds. Runoff curve numbers (CN) were determined based on soil group and cover. Curve numbers appropriate for scrub cover were used for areas of natural vegetation, and curve numbers appropriate for irrigated pasture were used for lawns and other irrigated ground cover. A curve number of 98 for antecedent moisture condition (AMC) II was used for all impervious areas. The runoff curve numbers used to calculate runoff varied between AMC I (with 1.4 inches or less during previous five days) and AMC III (with 2.1 inches or more during the previous five days) depending on the precipitation during the previous five days.

For each land use and soil group combination, runoff was determined for each day during the period of record. The following equations are used in the NRCS model:

$$R = \frac{(P - 0.2S)^2}{(P - 0.8S)}$$

Where P is the precipitation in inches, R is the runoff in inches, and S is the storage in inches:

$$S = \frac{1000}{CN} - 10$$

Rainfall Data for Monterey was obtained from NOAA gage USC00045795, Monterey, CA, for the period 10/1/1951 to 9/30/1998, and from gage USC00045802, Monterey WFO, for the period 10/1/1998 to 9/30/2013 (Table B-2). The average annual precipitation is 18.6 inches/year. The Lake El Estero drainage basin is 2,418 acres, or approximately 3.78 square miles (Figure A-1). Using the method described above, the total estimated runoff into Lake El Estero averages 268 acre-feet per year (Table B-3).

Runoff capture from Lake El Estero was estimated for two diversion options, as discussed below.

Option 1 is to divert water from the lake into the municipal sanitary sewer system (Figure A-2). SSMH D05-052 is located near the existing El Estero Stormwater Pump Station. This is a 21-inch vitrified clay pipe (VCP) sewer with a crown elevation lower than the water surface of the lake. Looking at the profile between this manhole and the MRWPCA Monterey Lift Station, the

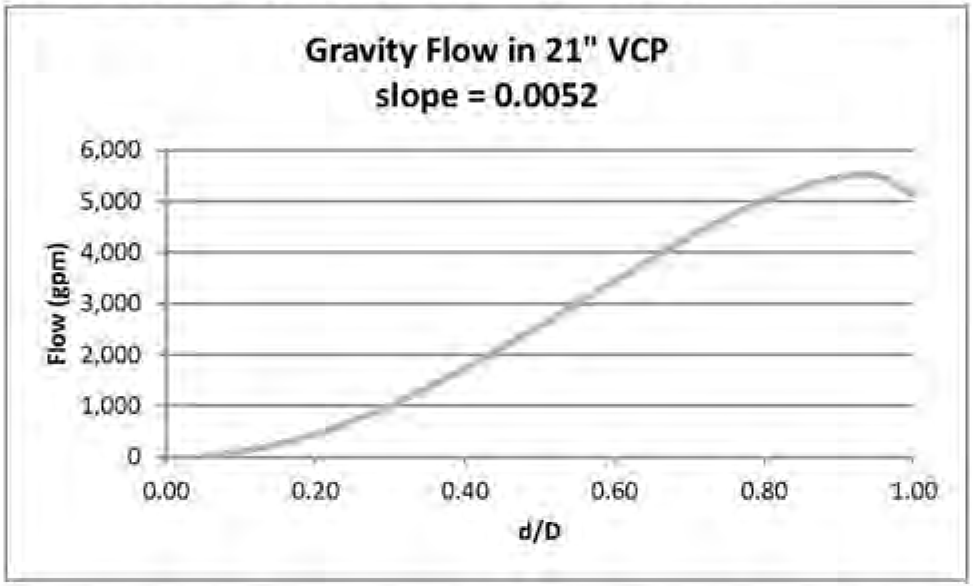
[2] Formerly the USDA Soil Conservation Service

limiting segment is a 21-inch VCP pipe at a slope of 0.0052 (Table 2-1). A flow monitor was installed in the pipeline during the months of November 2013 and January 2014 (see Appendix D). The observed peak dry weather flow (PDWF) in the pipeline was approximately 2,100 gpm. The peak wet weather flow (PWWF) was assumed to be 1.5 x PDWF = 3,100 gpm. Based on the pipeline slope and material, the capacity at d/D = 0.95 is estimated at 5,500 gpm (Figure 2.1), leaving an excess capacity of about 2,400 gpm for stormwater conveyance, or approximately 10.6 acre-feet/day. This diversion may be made with a gravity pipeline controlled by a motorized control valve.

**Table 2-1: Existing Sanitary Sewer Manholes and Pipelines**

| Upstream SSMH | Invert | Downstream SSMH | Invert | D (in) | L (ft) | Slope |
|---|---|---|---|---|---|---|
| D06-004 | -8.6 | D06-005 | -9.1 | 21 | 90 | 0.0056 |
| D06-005 | -9.1 | D05-052 | -10.89 | 21 | 223 | 0.0080 |
| D05-052 | -11.4 | D05-061 | -12.0 | 21 | 88 | 0.0068 |
| D05-061 | -12.0 | MRW-006 | -13.73 | 21 | 343 | 0.0052 |

**Figure 2.1: Capacity Curve for Limiting Sewer Segment**



Runoff capture from Lake El Estero was calculated based on two diversion limits. A lower limit of 5 acre-feet/day was assumed to be too small to initiate the runoff capture system (about three inches of rise in the 18-acre lake surface). The next 10.6 acre-feet were captured by the diversion system. Runoff in excess of 15.6 acre-feet/day was assumed to bypass the system and overflow to the bay. Using these limits, the estimated annual runoff capture was 87 AFY. This varied greatly based on the annual rainfall pattern, from a minimum of 0 AFY to a maximum of 224 AFY.

The City of Monterey and MRWPCA Staff conducted a two-day shunt test during the period February 24-26, 2014, to assess the effects of adding water from Lake El Estero to the municipal wastewater collection and treatment systems. A temporary pump was installed at the stormwater pump station and piped to SSMH D05-052. The pump operated at approximately 1,500 gpm for a period of 50 hours, transferring 4.5 million gallons. The inflow was reported to have caused minor surcharging at the receiving manhole due to the configuration of the temporary piping. Spills or surcharging were not reported for the limiting pipeline segment downstream.

Option 2 is to install a pump station and force main to divert flow directly to the MRWPCA Monterey Pump Station (MPS), which is approximately 0.75 miles from Lake El Estero. The MPS has a rated maximum day capacity of 20 MGD, but is currently using only 8 MGD on peak days, leaving an excess of 12 MGD, or 30 acre-feet/day (Figure A-3). Calculating the daily runoff capture using the same 5 AF/day minimum limit and increasing the maximum capture to 30 AF/day, the estimated annual capture volume is 140 AFY, with a range from 14 AFY (minimum) to 390 AFY (maximum). Although this yield is nearly twice that of the gravity diversion, the total yield is too small to justify the construction cost of a pump station and long force main.

The drainage basin adjacent to the west of the Lake El Estero drainage basin previously drained to the Lake, but was diverted directly to the bay with the construction of a box culvert in Figueroa Street. The connection to the lake may be restored to increase the volume of stormwater captured. This basin has an area of 1,186 acres (1.85 sq-mi). Soil types were identified using the NRCS Web Soil Survey, and land cover was estimated using the USGS 7.5 Minute Topographic Quadrangle for Monterey, CA (Table B-7). Runoff from the basin was estimated using the same method as for Lake El Estero (Table B-8). Although the basin is smaller, the average annual runoff is projected to be nearly equal to Lake El Estero (227 AFY in this basin, compared to 268 AFY in the Lake El Estero basin). The Figueroa basin has approximately the same amount of impervious cover (pavement and rooftops) as the El Estero basin, and the soil is predominantly Group D, which has a high runoff potential. The model results were checked against observed flow data for the Figueroa Box Culvert (see Appendix D). The single day results were within 5% of the metered flows. The multiple day results had a greater error, likely due to over-estimating the effects of antecedent rainfall.

The two areas were combined in a single model, and the runoff capture was recalculated (Tables B-9, 10 and 11). The average annual inflow to the Lake increased to 495 AFY, and the yield from the combined inflows was 136 AFY, an increase of 49 AFY over the Lake alone. To achieve this additional capture, the previous storm drain connection along Pearl Street must be reestablished. This connection should be configured with a by-pass weir, limiting the added inflow to the Lake to 4 ac-ft/day, or about 8 cfs, and allowing higher flows to overflow into the Figueroa Street box culvert. Routing all of the flows through the Lake would result in increased use of the existing stormwater pump station, which is an unnecessary cost.

## 2.2 In-Stream Flow Requirements

Lake El Estero is a land-locked water body which only discharges to the ocean during large storm events. There is no normal connection to the ocean nor a regular or consistent means of fish passage. The City's primary means of discharging water to the ocean is through their stormwater pump station at the northeast corner of the lake. This station moves water from the lake into a 48-inch pipeline that outfalls on Del Monte State Beach above the normal high water line. The pump station intake is screened to prevent fish from entering the station. The outfall structure is gated to prevent sand from accumulating inside the structure when not in use. If the pump station cannot divert the full volume of stormwater runoff entering the lake and the lake level rises sufficiently, water flows through two 33-inch gravity pipelines to a second point of discharge on Del Monte State Beach, west of the pump station outfall (see Figure A-2).

To the east of Lake El Estero is Del Monte Lake, which is a similarly land-locked water body. To the west, the City of Monterey stormwater collection system outfalls to the bay at several locations, the nearest being at the Municipal Wharf.

The City maintains the Lake El Estero water level for aesthetics and recreational use. The proposed project should not reduce the water levels below those currently maintained by the City. It should only reduce the volume of stormwater being discharged to the ocean.

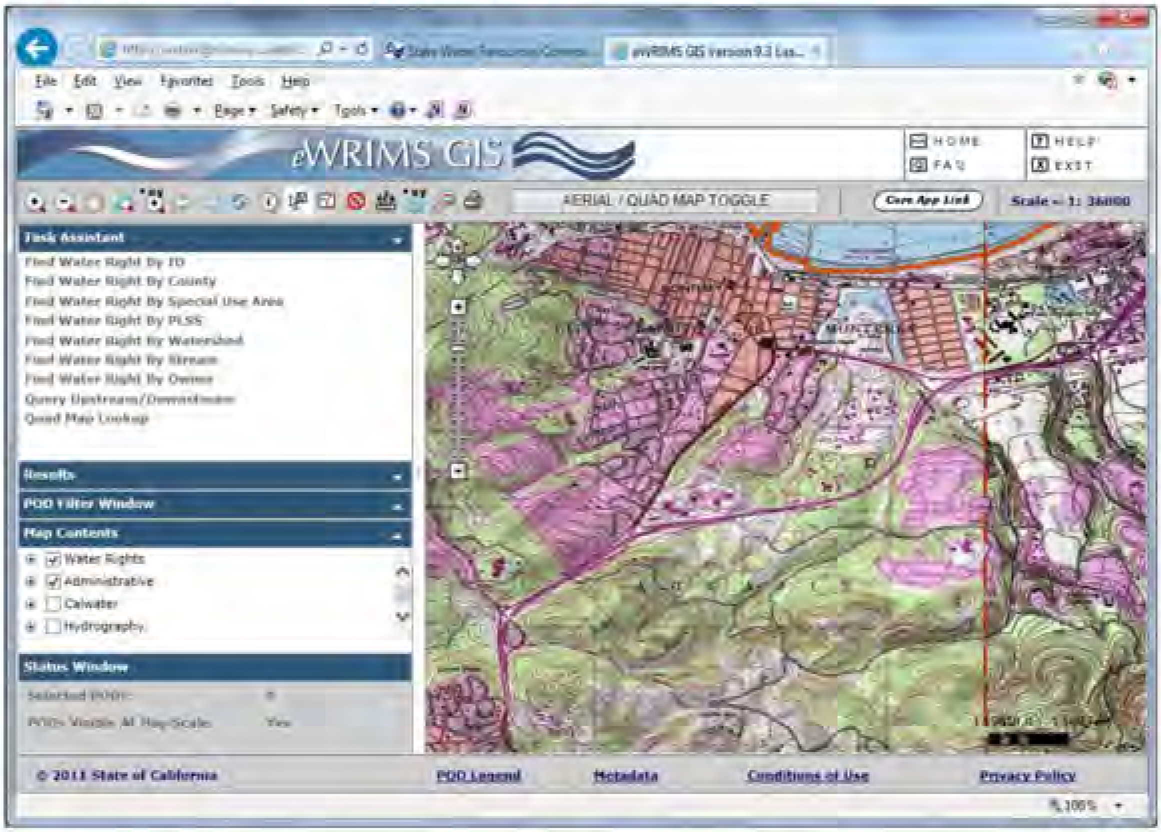
The Monterey Harbor and the Monterey Bay South Coastline are not classified as estuaries, so seasonal freshwater inflows are not required to maintain aquatic habitats. The Monterey Bay National Marine Sanctuary Final Management Plan was reviewed and no requirements for freshwater inflows to this portion of the Bay were listed. The reduction of urban stormwater inflows would be considered a marine water quality benefit because those flows currently carry pollutants into the Sanctuary.

## 2.3 Water Rights

It is not clear that a state water right would be required for the diversion of urban stormwater flows to the Proposed Project. The City of Monterey currently diverts water from the lake for irrigation within the surrounding park without a water right permit. That use may be considered a riparian claim, and therefore exempt from the formal permitting requirement. Existing water rights were researched to determine if any potential conflicts may exist.

The State Water Resources Control Board Electronic Water Rights Information Management System (eWRIMS) was queried to identify existing water rights in the Lake El Estero Watershed. The on-line GIS mapping tool was queried, and no Points of Diversion (PODs) within the Lake El Estero watershed were identified (Figure 2.2). A listing of all current water rights for Monterey County was obtained using a database query, and it also returned negative results for this area.

**Figure 2.2: SWRCB eWRIMS Interface**



The SWRCB Water Rights Order 98-08, Declaration of Fully Appropriated Stream Systems in California, identifies those stream segments which cannot support additional authorizations for diversion. The Carmel River is listed in that decision, but Lake El Estero and its tributary streams are not. There is no regulatory prohibition on requesting a water right from this source.

# Section 3 - Facility Requirements

## 3.1 Description and Sizing

Two conceptual designs were developed for stormwater diversion facilities from the Lake: a gravity connection to the sanitary sewer system controlled by a motorized valve and a pumped diversion with a short force main. The following design criteria and assumptions were used:

- The inlet may be located on the lake bank or within the existing pump station
- The inlet must be screened to minimize fish and trash capture
- The diversion pipeline will connect to the existing sanitary sewer manhole near the stormwater pump station (D05-052)
- The minimum velocity in the pipeline shall be 2 feet/second to prevent the settling of suspended sediments in the pipeline
- The maximum velocity in the pipeline shall be less than 8 feet/second to limit the friction losses
- If required, submersible pumps will be used

Two sets of conceptual design diagrams are provided in Appendix C.

The normal water level of the Lake is above the crown of the receiving sanitary sewer main, so the first option considered was a gravity connection (Figures 1 and 2 in Appendix C). This proposed facility would be configured with a new gravity inlet located on the lake bank, equipped with a fish screen, a 12-inch gravity pipeline connecting to SSMH D05-052, a flow meter, a motorized control valve, and a check valve. The discharge pipe would be above the crown of the existing pipe connections in the manhole to provide an air-gap between the sanitary system and the lake. A control panel will be required to operate the motorized valve. It may be configured as autonomous, looking at a lake level sensor and the flow meter, or it may connect to the MRWPCA SCADA system and be controlled remotely. Because the system will be discharging to the municipal sanitary sewer, pressure transducers or float switches must be installed in the receiving system to shut off this system if the receiving sewer is flowing full.

The second option considered was a pumped connection (Figures 3 and 4 in Appendix C). Pumping the water will have a higher operating cost than a gravity connection, but offers positive flow control. This option is configured as adding a column-type pump in the existing pump station wet well, and a similar discharge pipeline with a check valve and flow meter as in the first option.

The screened inlet must be sized to allow full flow through the screen with a maximum velocity of 1 ft/s to allow fish to escape. Assume the screen has an open area of 50%, and that 50% of the screen is blinded by trash/vegetation. For a maximum flow of 5.3 cfs (= 2,400 gpm):

$A_{screen}$ = 5.3 cfs / [(1 ft/s) x (50% screen openings) x (50% blinded)] = 21.2 sq-ft

Minimum dimensions: 4-ft wide x 5.3-ft long

For a new inlet, the Lake bank at the pipe penetration should be lined with rock or concrete to prevent erosion. If rock is used, a concrete cut-off collar should be cast around the pipeline to prevent water from migrating through the pipe bedding material. An alternative option would be to core-drill through the wall of the existing pump station wet well for the new inlet. The existing station uses diesel drives for the pumps, and the fuel tank and pipeline are located underground between the wet well and the receiving sanitary sewer, preventing the installation of a new pipeline at a uniform slope, so this inlet configuration was not used for the gravity option.

The pipeline would be a 12-inch PVC (AWWA C-900 pressure pipe). The size was selected based upon the calculated velocity and friction losses in the pipeline. It was assumed that the lake would provide a minimum of 5-feet of static head between the inlet and discharge. A 12-inch main flowing at 2400 gpm would have a velocity of 6.8 feet per second and estimated losses totaling 3.6 feet (Table C-1). A 10-inch main would have estimated losses totaling 7.6 feet, which exceeds the available system head. The pipeline should be installed with a minimum of 3-feet of cover in the pipe trench.

For the pumped option, an axial flow or column-type pump is recommended. A column may be added to the existing wet well, suspended from the pump deck and braced to the wall. The discharge piping may pass through the wall of the wet well (as shown in the diagram), or it may extend over the pump deck and then go underground. The lake provides a substantial forebay for the pump station, so a variable speed drive will not be required to match the incoming flow rate. Using a 12-inch discharge pipeline, the system horsepower requirement is only 5.3 hp. However, pumps of this type are typically sized for larger flows. The closest match found using the Flygt pump catalog was a 27 hp pump, model PL 7020 with a trimmed impellor to meet the low design point.

The proposed facilities are in a FEMA floodplain[3]. The proposed submersible pumps will not be affected by storm inundation, but the electrical power and control equipment must be elevated above the base flood elevation of 11-ft (approximately 2-ft above the existing pump station deck).

[3] FEMA Flood Insurance Rate Map, Panel 06053C0703G, April 2009 (see Appendix A)

### 3.2 Costs

Capital costs were estimated for the two transfer station configurations, gravity and pumped. Detailed estimates are provided in Tables C-3 and C-4 in Appendix C. Non-construction costs (design, permitting, legal, etc.) were estimated as 40% of the construction cost.

The condition of the existing box culvert in Pearl Street at Figueroa Street is unknown (was it bricked closed or physically removed), so no estimate was made of the cost to reconnect the adjacent drainage basin to Lake El Estero.

Right-of-way acquisition costs were not included in the capital cost estimates. The proposed site is on City of Monterey property, so standard encroachment fees should apply.

**Table 3-1: Estimated Capital Costs**

| | El Estero Gravity | El Estero Pump Station |
|---|---|---|
| Estimated Construction Cost | $65,800 | $157,900 |
| Inspection and Testing (15%) | $10,000 | $24,000 |
| Construction Contingency (20%) | $13,000 | $32,000 |
| Estimated Total Construction Cost | $89,000 | $214,000 |
| | | |
| Design, Permitting, Legal (40%) | $35,600 | $85,600 |

Costs are in 1st Quarter 2014 dollars

The City of Monterey has standard capacity charges and monthly fees for connecting to the sanitary sewer collection system, which should apply to this connection. Similarly, the MRWPCA has standard capacity charges for connection to the regional wastewater system that are based on the flow rate, the biological oxygen demand (BOD) and the suspended solids concentration, and monthly charges for wastewater treatment. These fees are not included in this estimate, because the MRWPCA is a sponsor of the Proposed Project. The primary, secondary and advanced treatment costs for this source of supply will appear in the overall project cost analysis.

Annual operating and debt service costs for each configuration were estimated using the following planning factors:

- Debt service assumes a 30-year bond at 4% annual interest
- Annual operation and maintenance of pump stations is estimated at 2.5% of the capital cost
- Annual operation and maintenance of pipelines is estimated at 1% of the capital cost
- Electrical power cost is assumed at $0.16 per kWh
- Assume the station operates 13.5 days per year (average from runoff capture model)

The factors above provide an order-of-magnitude estimate of annual costs, which may be used in comparing project configurations. The estimated annual costs are provided below.

**Table 3-2: Estimated Annual Costs, Gravity Option**

| Category | Basis | Annual $ |
|---|---|---|
| **Capital Repayment** | | |
| Assume 30-year bond at 4% | $146,000.00 | $8,443.19 |
| **Annual Operation and Maintenance** | | |
| Assume 2.5% of Pump Station Capital Cost | $0.00 | $0.00 |
| Assume 1.0% of Pipeline Capital Cost | $146,000.00 | $3,650.00 |
| **Electrical Power** | | |
| Number of operating days/year | 13.5 | |
| Pumps: None | | |
| Estimated annual kWh | - | |
| Assumed cost per KWH | $0.16 | $0.00 |
| **Total Estimated Annual Cost** | | **$12,100.00** |

**Table 3-3: Estimated Annual Costs, Pump Station Option**

| Category | Basis | Annual $ |
|---|---|---|
| **Capital Repayment** | | |
| Assume 30-year bond at 4% | $214,000.00 | $12,375.64 |
| **Annual Operation and Maintenance** | | |
| Assume 2.5% of Pump Station Capital Cost | $200,500.00 | $5,012.50 |
| Assume 1.0% of Pipeline Capital Cost | $13,500.00 | $337.50 |
| **Electrical Power** | | |
| Number of operating days/year | 13.5 | |
| Pumps: 27 HP (0.7457 kW/hp) | 20.1 | |
| Estimated annual kWh | 6,523 | |
| Assumed cost per KWH | $0.16 | $1,043.74 |
| **Total Estimated Annual Cost** | | **$18,800.00** |

# Section 4 - Water Quality

## 4.1 Summary of Current Condition

The Central Coast Regional Water Quality Control Board (CCRWQCB) Water Quality Control Plan for the Central Coast Basin (Basin Plan) designated beneficial uses of the Lake El Estero as including municipal and domestic supply, groundwater recharge, water contact recreation, non-contact water recreation, wildlife habitat, cold water fish habitat, warm water fish habitat, spawning/reproduction/early development habitat and commercial or sport fishing. Many of these are the minimum uses listed for all inland water bodies within the region, unless specific water quality information caused the RWQCB to remove a specific use (e.g., not listing water contact recreation for a stream segment listed for fecal coliform contamination). The Monterey Harbor has designated beneficial uses of water contact recreation, non-contact water recreation, industrial service supply, navigation, marine habitat, shellfish harvesting, commercial or sport fishing and rare/threatened/endangered species habitat.

Lake El Estero is not listed as an impaired water body, but Majors Creek (at tributary stream to Lake El Estero) and the Monterey Harbor are listed. Majors Creek is listed as impaired water body pursuant to Section 303(d) of the Clean Water Act for copper, lead, zinc and Escherichia coliform. The Monterey Harbor is listed as an impaired water body for metals and sediment toxicity. Water quality has been sampled and monitored for the past 15 years under various programs, including the Central Coast Long-term Environmental Assessment Network (CCLEAN), the Monterey Bay Sanctuary Citizen Watershed Monitoring Network and the City of Monterey Urban Watch. The results of these programs have been consolidated in Table B-12, for Lake El Estero, Majors Creek, Monterey Harbor and Monterey Bay South Coastline. Sampling locations are shown on Figure A-5.

The Monterey Regional Storm Water Management Program identifies water quality objectives for stormwater discharging into the Monterey Bay. These and other applicable water quality standards are consolidated in Table B-13, Water Quality Objectives.

### 4.2 Effect of Diversion on Monterey Bay Water Quality

Stormwater runoff can carry pollutants such as oils, sediments and metals into the Monterey Bay, which is a National Marine Sanctuary. Lake El Estero serves as a settling basin for stormwater, which is a treatment process. Water passing through the lake carries lower levels of suspended solids than stormwater discharging directly to the Bay. Samples of the water discharged through the Lake El Estero stormwater pump station have not been collected and tested, but looking at the available water quality data in Table B-7, it may be inferred that these discharges will be of better quality than direct discharges from other portions of the municipal system. Therefore, the proposed diversion should have a little to no effect on the Bay.

Reconnecting the adjacent drainage basin to Lake El Estero through the Pearl Street box culvert should have a positive effect on near-shore water quality. Passing these flows through the lake will provide settling of suspended solids. During peak rain events, the addition of these flows to the lake will cause increased use of the stormwater pump station. The increased inflow rates will decrease the detention time in the lake, leading to a decline in water quality during stormwater pumping periods. However, the quality of the pumped discharge will be better than the current quality of flows directly discharged to the Bay.

Adding stormwater to the sanitary sewer system increases the risk of sanitary sewer overflows, which can convey bacterial pollutants into the Bay. The sanitary sewer pipeline between Lake El Estero and the MRWPCA interceptor will flow at maximum capacity during peak diversions, so certain safeguards should be included in the project. First, the sewer pipeline and manholes should be inspected for cracks and leaking joints. If found, they should be repaired to prevent the combined flows from leaking out into the surrounding soil. Second, pressure sensors should be installed in one or more manholes to identify backwater effects in the system. If the combined storm and sewer flow exceeds the gravity capacity of the sewer main, the stormwater system can shut off to prevent the sanitary flows from spilling. The stormwater can be held in the lake for later diversion or discharged through the stormwater pump station, depending upon the level of the lake at the time.

Figure A-4 (continued)

## Definitions of FEMA Flood Zones

Flood zones are geographic areas that FEMA has defined according to varying levels of flood risk and type of flooding. These zones are depicted on the published Flood Insurance Rate Map (FIRM) or Flood Hazard Boundary Map (FHBM).

## Special Flood Hazard Areas – High Risk

Special Flood Hazard Areas represent the area subject to inundation by 1-percent-annual chance flood. Structures located within the SFHA have a 26-percent chance of flooding during the life of a standard 30-year mortgage. Federal floodplain management regulations and mandatory flood insurance purchase requirements apply in these zones.

| ZONE | DESCRIPTION |
|---|---|
| A | Areas subject to inundation by the 1-percent-annual-chance flood event. Because detailed hydraulic analyses have not been performed, no Base Flood Elevations (BFEs) or flood depths are shown. |
| AE, A1-A30 | Areas subject to inundation by the 1-percent-annual-chance flood event determined by detailed methods. BFEs are shown within these zones. (Zone AE is used on new and revised maps in place of Zones A1–A30.) |
| AH | Areas subject to inundation by 1-percent-annual-chance shallow flooding (usually areas of ponding) where average depths are 1–3 feet. BFEs derived from detailed hydraulic analyses are shown in this zone. |
| AO | Areas subject to inundation by 1-percent-annual-chance shallow flooding (usually sheet flow on sloping terrain) where average depths are 1–3 feet. Average flood depths derived from detailed hydraulic analyses are shown within this zone. |
| AR | Areas that result from the decertification of a previously accredited flood protection system that is determined to be in the process of being restored to provide base flood protection. |
| A99 | Areas subject to inundation by the 1-percent-annual-chance flood event, but which will ultimately be protected upon completion of an under-construction Federal flood protection system. These are areas of special flood hazard where enough progress has been made on the construction of a protection system, such as dikes, dams, and levees, to consider it complete for insurance rating purposes. Zone A99 may be used only when the flood protection system has reached specified statutory progress toward completion. No BFEs or flood depths are shown. |

Figure A-4 (continued)

## Coastal High Hazard Areas – High Risk

Coastal High Hazard Areas (CHHA) represent the area subject to inundation by 1-percent-annual chance flood, extending from offshore to the inland limit of a primary front al dune along an open coast and any other area subject to high velocity wave action from storms or seismic sources. Structures located within the CHHA have a 26-percent chance of flooding during the life of a standard 30-year mortgage. Federal floodplain management regulations and mandatory purchase requirements apply in these zones.

| ZONE | DESCRIPTION |
|---|---|
| **V** | Areas along coasts subject to inundation by the 1-percent-annual-chance flood event with additional hazards associated with storm-induced waves. Because detailed coastal analyses have not been performed, no BFEs or flood depths are shown. |
| **VE, V1-V30** | Areas along coasts subject to inundation by the 1-percent-annual-chance flood event with additional hazards due to storm-induced velocity wave action. BFEs derived from detailed hydraulic coastal analyses are shown within these zones. (Zone VE is used on new and revised maps in place of Zones V1–V30.) |

## Moderate and Minimal Risk Areas

Areas of moderate or minimal hazard are studied based upon the principal source of flood in the area. However, buildings in these zones could be flooded by severe, concentrated rainfall coupled with inadequate local drainage systems. Local stormwater drainage systems are not normally considered in a community's flood insurance study. The failure of a local drainage system can create areas of high flood risk within these zones. Flood insurance is available in participating communities, but is not required by regulation in these zones. Nearly 25-percent of all flood claims filed are for structures located within these zones.

| ZONE | DESCRIPTION |
|---|---|
| **B, X (shaded)** | Moderate risk areas within the 0.2-percent-annual-chance floodplain, areas of 1-percent-annual-chance flooding where average depths are less than 1 foot, areas of 1-percent-annual-chance flooding where the contributing drainage area is less than 1 square mile, and areas protected from the 1-percent-annual-chance flood by a levee. No BFEs or base flood depths are shown within these zones. (Zone X (shaded) is used on new and revised maps in place of Zone B.) |
| **C, X (unshaded)** | Minimal risk areas outside the 1-percent and .2-percent-annual-chance floodplains. No BFEs or base flood depths are shown within these zones. (Zone X (unshaded) is used on new and revised maps in place of Zone C.) |

## Undetermined Risk Areas

| ZONE | DESCRIPTION |
|---|---|
| **D** | Unstudied areas where flood hazards are undetermined, but flooding is possible. No mandatory flood insurance purchase requirements apply, but coverage is available in participating communities. |

This is based on only runoff in excess of 5 acre-feet in one day being transferable.
A maximum of 10.6 acre-feet from one day of runoff may be transferred to the MRWPCA system.

Water Year Type based on Salinas Airport Gage, Dry < 25th percentile, Wet > 75th percentile

| Average by Type | |
|---|---|
| Wet | 147 |
| Normal | 85 |
| Dry | 48 |

| **25th Percentile** | 0 | 0 | 1 | 6 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 63 |
| **50th Percentile** | 0 | 7 | 10 | 27 | 12 | 12 | 0 | 0 | 0 | 0 | 0 | 0 | 103 |
| **75th Percentile** | 9 | 20 | 36 | 58 | 35 | 33 | 7 | 0 | 0 | 0 | 0 | 0 | 188 |
| **Average** | 5 | 16 | 23 | 40 | 23 | 21 | 8 | 1 | 0 | 0 | 0 | 1 | 140 |
| **Minimum** | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 14 |
| **Maximum** | 31 | 85 | 96 | 169 | 209 | 118 | 96 | 24 | 12 | 4 | 0 | 59 | 508 |

This is based on only runoff in excess of 5 acre-feet in one day being transferable.
A maximum of 30 acre-feet from one day of runoff may be transferred to the MRWPCA system.

This is based on only runoff in excess of 5 acre-feet in one day being transferable.
A maximum of 10.6 acre-feet from one day of runoff may be transferred to the MRWPCA system.

Water Year Type based on Salinas Airport Gage, Dry < 25th percentile, Wet > 75th percentile

| **Average by Type** | |
|---|---|
| Wet | 220 |
| Normal | 134 |
| Dry | 81 |

Table B-12: Lake El Estero and Monterey Bay Water Quality

| Stream | Location | Analyte Name | No. Samples | Units | Mean | Min | Max |
|---|---|---|---|---|---|---|---|

## Appendix D: Flow Monitoring

### D1. Sanitary Sewer at Lake El Estero

Schaaf & Wheeler conducted sewer flow monitoring of the City of Monterey Sanitary Sewer at Lake El Estero. A depth monitor and data logger was installed on the sewer pipeline exiting manhole D05-052, located next to the Stormwater Pump Station, on November 12, 2013. The initial installation was not secure, and the monitor was reset on November 22, 2013. Data was downloaded from the monitor on several occasions. It was removed on February 24, 2014.

The data logger records the depth of water in the pipeline at set time intervals. The depth of water was converted to flow using Manning's equation:

$$V = \left(\frac{1.486}{n}\right) R^{2/3} S^{1/2}$$

Where:

V= velocity in feet/second
n = roughness coefficient
R = hydraulic radius
S = slope of the pipeline

The pipe roughness coefficient was assumed to be 0.013 for sewer pipe. The hydraulic radius is equal to the wetted perimeter of the pipe divided by the cross-sectional area of flow, which were calculated based on depth of flow and the pipeline diameter of 21-inches. The pipeline slope was calculated as 0.0068 based on the invert of SSMH D05-052 at -11.4 feet, the invert of SSMH D05-061 at -12.0-feet, and the pipeline length of 88-feet. The flow quantity was calculated by multiplying the flow velocity by the cross-sectional area of flow.

The data set and graph include several flow spikes where the instantaneous flow greatly exceeds the normal curve. These are likely caused by debris hanging up on the monitor or the mounting bracket and may be disregarded.

Based upon the monitoring, the average daily sewer flow at this location is 1,140 gallons per minute or 1.6 million gallons per day. The peak hourly flow was approximately 2,100 gpm. There were no significant rain events during the monitoring period, so these results should be considered Average and Peak Dry Weather Flows.

**D2. Figueroa Box Culvert**

Schaaf & Wheeler conducted storm sewer flow monitoring in Pearl Street above Figueroa Street in Monterey. A depth monitor and data logger was installed in the storm drain downstream of Pearl Street. The gage was active from November 26, 2013, to March 28, 2014. During that period there was limited rainfall. The two-day storm of February 28 – March 1, 2014 was used as a calibration check for the runoff prediction model.

The data logger collected water depth at a one-minute time step. Depth was converted to flow using Manning's equation and the following parameters: Pipe roughness of n = 0.013, slope = 0.0071 ft/ft, box width 9-ft, box height 4.5-ft at center and 4.25-ft at sides (valley gutter at invert). Cumulative flow was totaled and converted to acre-feet. Totals for the 2-day storm were compared to the modeled outputs:

| Date | Precipitation (in) | Metered Flow (ac-ft) | Modeled Flow (ac-ft) |
|---|---|---|---|
| 2/28/2014 | 1.38 | 23.1 | 23.7 |
| 3/1/2014 | 0.98 | 11.7 | 30.3 |

Modeled results for the first day were within 5% of the metered daily flow, which was better than expected. The modeled results for the second day were almost 300% of the metered flow. The majority of the flows on both days are from the hardscape. The difference between the two on 3/1/14 was due the model's adjustment of the curve numbers based on the cumulative precipitation in the preceding 5 days. The model applied below-average curve numbers for the condition on 2/28/14 and matched the observed flows. It applied above-average curve numbers for the condition on 3/1/14. This error does not affect the stormwater capture model, which by-passes peak flows above 15.6 ac-ft/day. Therefore, the runoff model was not adjusted.

# Predicted Impact on Farming from Use of Recycled Water with Higher Salinity

## EXECUTIVE SUMMARY

The proposed Pure Water Monterey Groundwater Replenishment Project (proposed project) is a water supply project that will serve northern Monterey County. The project includes the collection of a variety of new source waters that would be combined with existing incoming wastewater flows for conveyance to and treatment at the Monterey Regional Water Pollution Control Agency's Regional Wastewater Treatment Plant (RTP). The effluent would be further treated at a new advanced water treatment facility to produce highly-purified recycled water for injection into the Seaside Groundwater Basin (and later extraction for replacement of existing municipal water supplies) and to provide additional tertiary recycled water for agricultural irrigation in northern Salinas Valley as part of the Castroville Seawater Intrusion Project (CISP).

Water quality guidelines critical to plant growth and development include salinity (as measured by total dissolved solids or electrical conductivity, sodicity (represented by a non-dimensional parameter called Sodium Adsorption Ratio), and specific ions (primarily sodium, chloride, and boron). Salinity is the most critical of these criteria with regard to its impact on farming under the conditions prevailing in the CSIP service area and the recycled water blend scenarios anticipated in the future as part of the proposed project.

The addition of new source waters for the proposed project is likely to increase the salinity of recycled water above that currently produced at the RTP. This change in water quality is not expected to impact the farming activities within the CSIP service area to a significant extent, mainly because of the various management tools and expertise available to the growers, some of which are already in practice. It is estimated that the increased salinity of the recycled water resulting from the blend of existing raw wastewater with the new source waters may result in a 13% reduction in total crop production value in the CSIP service area under a drought year scenario only under two conditions (1) if Salinas River water is not available for dilution with recycled water for irrigation and (2) if salinity control crop management practices are not implemented to maintain yield. The calculations leading up to this conclusion are based on agronomic and soil science literature combined with data from local conditions, holding all other variables constant. To maintain the integrity of these calculations, all other factors are assumed unchanged, even though in practice, that would not be the case. In practice, the potential loss of crop value would be ameliorated by the implementation of standard strategies and management practices to address higher salinity levels in irrigation water sources.

Recycled water currently is blended with Salinas River water during most parts of the year (April 1 through October 31) and in most years, except following multiple drought years, before delivery to the growers. This practice is expected to continue in the future. Therefore, few—if any—of the growers will be irrigating with a straight blend of recycled water at all times. Salinas River water has a much lower salinity than any of the new source waters that will become recycled water (except the storm water). Of the new source waters to be used for the proposed project, Agricultural Wash Water will be the highest volumetric contributor and has higher salinity than the current recycled water. Thus, timing of the Agricultural Wash Water contribution to the RTP is important when understanding the effects of blending recycled water with Salinas River water. Significantly, the greatest extent of blending with Salinas River water and with the recycled water containing Agricultural Wash Water is expected to occur during the peak summer period when plants would be growing at the highest rate and would benefit the most from a reduced salinity level.

It is the considered opinion of the author that the potential losses in crop production can and will be mitigated with irrigation management practices, such as additional leaching fraction, modified irrigation scheduling, and addition of amendments as described further below in this technical memorandum.

# Predicted Impact on Farming from Use of Recycled Water with Higher Salinity

## INTRODUCTION

The coastal lands in northern Monterey County are some of the most fertile agricultural areas in the State of California. Combined with an ideal climate for growing a large variety of food crops, this area is an economic powerhouse. The Monterey County Agricultural Commissioner's 2013 Crop Report (MCAC 2013) estimates that the annual value of agricultural products from the County is $4.4 billion. Growers in the Castroville Seawater Intrusion Project (CSIP) service area have been growing high value crops under a recycled water irrigation regime for the past 17 years. With the choice of crop varieties, management practices, and a sophisticated irrigation management system there have been no complaints about yield, quality of crops, or sales of crops sent to market. In fact, the availability of recycled water has ensured the continued cultivation of high-value crops in this region. Recycled water has served as a valuable regional resource to replace groundwater wells that historically provided irrigation water, but were abandoned as a result of seawater intrusion caused by overdraft of the local aquifers.

The proposed Pure Water Monterey Groundwater Replenishment Project (proposed project) is a water supply project that will serve northern Monterey County. The project includes the use of new source waters that would be combined with existing incoming wastewater flows for conveyance to, and treatment at, the Monterey Regional Water Pollution Control Agency's Regional Wastewater Treatment Plant (RTP). The effluent from the RTP would be further treated at a new advanced water treatment facility to produce highly-purified recycle water for injection into the Seaside Groundwater Basin (and later extraction for replacement of existing municipal water supplies) and treated through the SVRP to provide additional tertiary recycled water for agricultural irrigation in northern Salinas Valley. The new source waters would include the following: 1) water from the City of Salinas agricultural wash water system, 2) stormwater flows from the southwestern part of Salinas and the Lake El Estero facility in Monterey, 3) surface water and agricultural tile drain water that is captured in the Reclamation Ditch and Tembladero Slough, and 4) surface water and agricultural tile drain water that flows in the Blanco Drain.

The purpose of this technical memorandum (TM) is to assess the impact of introduction of additional source waters on farming resulting from the anticipated increase in the salinity of disinfected tertiary recycled water. An increase in the salinity of recycled water could result in yield reduction of crops grown with recycled water unless specific management practices are implemented to account for the change in salinity levels in the recycled water. Such adjustments to management practices may be costly, may not be fully effective, or may have additional adverse impacts of their own. The added cost elements may include extra water application commonly applied with each irrigation to increase the leaching fraction. It may also include the material and labor costs of amendments, such as gypsum to increase soil permeability, which would allow free movement of the extra water past the plant root zone. Another cost element that may be required is additional tile drain installation.

For the purposes of calculating impacts of increased salinity on crop production, it was assumed that the current scenarios and management practices would not change in the future.

## WATER QUALITY AND FARM PRODUCTIVITY

A one-year monitoring program from July 2013 to June 2014 was conducted for five of the potential source waters for the proposed project. Monthly and quarterly sampling was carried out for the RTP secondary effluent, agricultural wash water, and Blanco Drain drainage water. Limited sampling of stormwater from Lake El Estero was performed due to seasonal availability, and there was one sampling event for the Tembladero Slough drainage water.

The agronomic water quality parameters of the greatest importance with regard to sustainable soil productivity and maximum crop yield potential along with applicable guidelines are shown in first four rows of Table 1, and can be found in standard agronomic and soil science literature (e.g., FAO, 1976). Inorganic salts will not be removed during primary or secondary treatment at the RTP, or during tertiary treatment/disinfection, and thus it is possible to calculate a predicted concentration (Blended Mix) based on the volumetric contributions of each source water and their constituent concentrations. The 5th through 10th rows in Table 1 present the median concentrations for each parameter for each source water. The last row (Blended Mix) presents the calculated predicted concentration of each parameter for the blend of the source waters at a time when their impact might approach worst-case scenario. As described more fully in the section below titled "Salinity of Blended Water," the Phase B drought scenario of source water blends reflects this worst-case.

With the exception of chloride, the other parameters fall within the green zone (generally safe). Chloride, at a Blended Mix concentration of 264 mg/L falls within the red (problem) zone and would require some management on the part of the growers. However, the existing recycled water comprised of municipal wastewater has the same average chloride concentration, and thus the Blended Mix recycled water quality would be the same, not necessitating changes in management practices or impacts on crops.

Potassium chloride is used as a soil amendment in the Salinas Valley as a fertilizer to replenish the essential macronutrient, potassium. As a result of increasing levels of chloride, detected in the soil in recent years, it was recommended that growers use alternative potassium amendments, such as potassium thiosulfate or potassium sulfate. More recent monitoring in recent years has shown a steadily declining level of chloride in the CSIP area soils (Platts, 2015).

***Table 1 Water Quality Parameters of Agronomic Relevance in Irrigation of Agricultural Crops***

| Sustainability Guidelines | Salinity (EC) dS/m[1] | Sodium Adsorption Ratio (SAR) | Sodium, mg/L[2] | Chloride, mg/L | Boron, mg/L |
|---|---|---|---|---|---|
| **Generally No Problem** | **0.5 - 2.0** | **<6** | **< 70** | **<100** | **<0.5** |
| **Slight to Moderate Problem** | **2.0 - 4.0** | **7 - 9'** | **70 - 230** | **100 - 250** | **0.5 - 5** |
| **Problem** | **> 4.0** | **>9** | **>230** | **>250** | **>5** |
| **Source Waters** | **Average Values of Parameters** | | | | |
| **Municipal Wastewater** | 1.44 | 4.75 | 174 | 264 | 0.31 |
| **Agricultural Wash Water** | 1.59 | 4.15 | 177 | 237 | 0.23 |
| **Blanco Drain** | 2.84 | 3.32 | 241 | 274 | 0.66 |
| **Lake El Estero** | 2.56 | 4.96 | 235 | 423 | 0.18 |
| **Tembladero Slough** | 2.94 | 4.41 | 333 | 394 | 0.51 |
| **Reclamation Ditch** | 1.17 | 2.45 | 96 | 130 | 0.51[3] |
| **Blended Mix[4]** | 1.75 | 4.75 | 174 | 264 | <0.5 |

1. EC – electrical conductivity; dS/m – deci Siemans per meter.
2. mg/L – milligrams per liter.
3. Reclamation Ditch boron is assumed to be equal to the concentration of boron in Tembladero Slough since they are both part of the same ditch system.
4. These water quality parameters reflect the worst-case scenarios of source water flow diversions for the purpose of assessing water quality of the treated secondary effluent/tertiary-treated water (i.e., Phase B in a drought year). Under all other Phases and scenarios, these values would be less.

As can be seen from a comparison of the value of each parameter with the corresponding guidelines in Table 1, some source waters fall in the problem range if used unblended with other sources. However, in the drought year, Phase B blended scenario (see discussion about this scenario, below), the average values, under blending scenarios considered, are in the safe range, with the exception of chloride. But as noted above, the predicted Blended Mix chloride concentration is equivalent to the current recycled water concentration.

Data for boron is provided in Table 1 because boron is an essential nutrient for plant growth and development at very low concentrations. However, at concentrations indicated to be problematic in Table 1, it can be toxic and cause severe damage to plants. While the current levels of boron in the recycled water (i.e., RTP effluent) and other potential source waters are not problematic in the blend, it may change in the future should the Monterey Peninsula Water Supply Project be implemented. It is a proposed ocean desalination project that would produce between 9.6 million gallons per day (mgd) to 6.4 mgd of water to be added to the region's water supply. The desalinated ocean water could increase the concentration of boron in recycled water by as much as 0.1 mg/L. If the increase is limited to this prediction, the blend will still be safe for irrigation. If the boron level in the blend rises to problematic ranges, additional actions would be needed to maintain the boron levels below the 0.5 mg/L guideline.

Aside from this overall evaluation of water quality parameters, there are two major additional concerns that must be addressed: (1) salinity, and (2) SAR. The impacts of salinity on crop yield are the most important consideration and are evaluated in most of the remainder of this TM.

Sodium adsorption ratio is a unitless parameter derived from the following empirical formula:

$$SAR = \frac{Na}{\sqrt{\frac{Ca+Mg}{2}}}$$

wherein concentrations of each of the ionic species (sodium [Na], calcium [Ca], and magnesium [Mg]) are expressed as meq/L. SAR is a measure of the potential for impact on soil permeability. A high SAR is indicative of problems in infiltrating water into the soil profile. However, the impact potential of SAR in a given irrigation water source is strictly related to the salinity of that irrigation water. This interdependence is best described by the graphic depiction[1] in Figure 1. Plotting the intersection of electrical conductivity (EC) and SAR for each source water indicates that none of the source waters (singly or in the Mixed Blend), as irrigation water, are problematic in terms of long-term potential impact on soil infiltration rate. This conclusion is consistent with findings of a long-term field study of recycled water impacts on the soils of CSIP service area (Platts, 2014A):

> "*Our analysis of study data from 2000 to 2012 supports the general conclusions of the MWRSA in the 1980s: The use of recycled water has caused an increase in soil salinity in the area; however, SAR values are not deleterious and Na has shown little accumulation in the rooting zone (1 to 12 inches)*."

Over a ten-year period of irrigation with a blend of varying proportions of recycled water and river water, moderate increases in salinity, sodium, chloride, and SAR in the soil solution were recorded. The increase in chloride was of particular interest and concern. A second paper in the same publication (Platts, 2014B) documents the critical role that annual rainfall plays in ameliorating salt impacts by leaching the salts and preventing accumulation in the root zone.

[1] This graphic depiction is commonly used in the classic agronomic literature and textbooks, such as Grattan (2002).

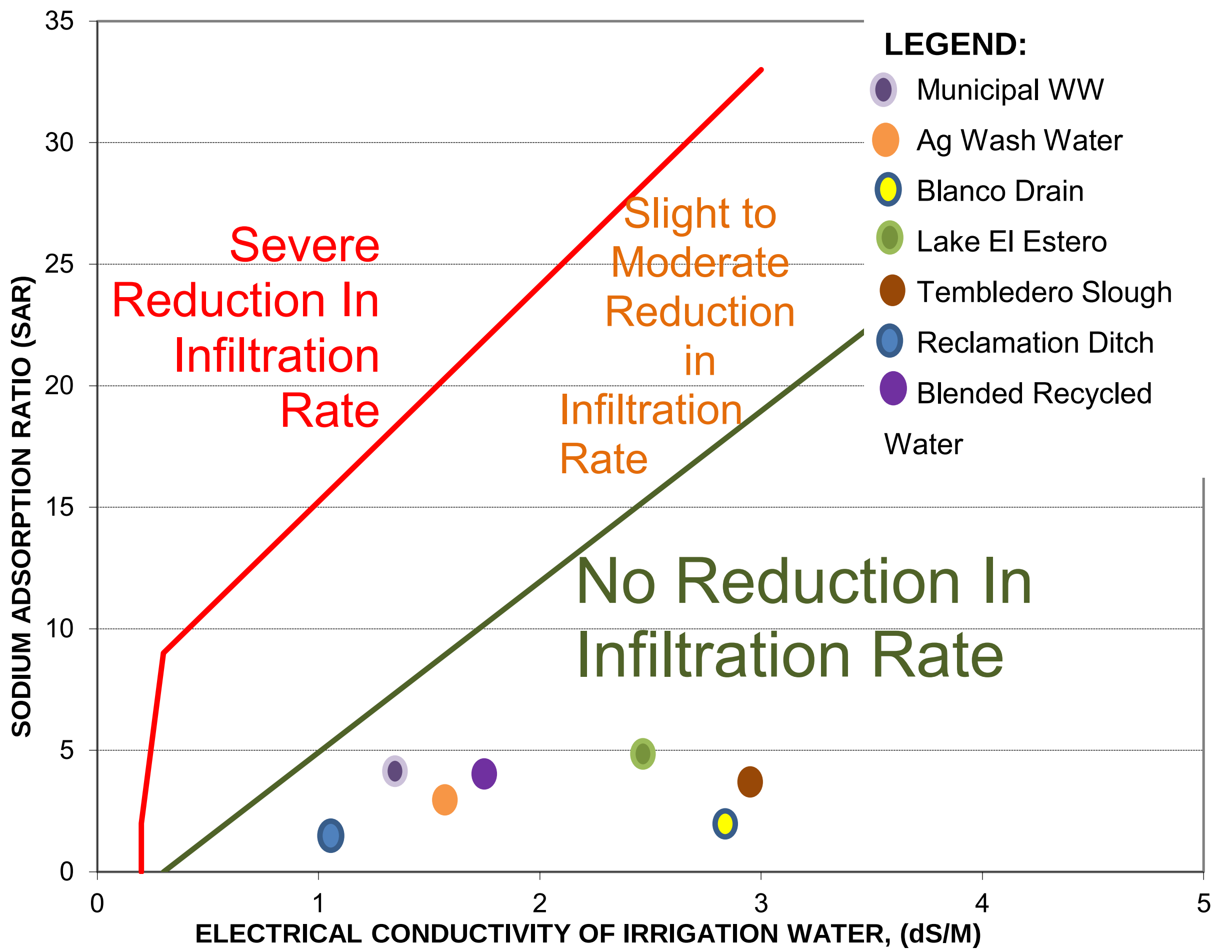

***Figure 1 Potential for Impact on Soil Infiltration Rate As a Result of Irrigation with Undiluted Source Waters and Blended Mix***

## SALINITY OF IRRIGATION WATER

Salinity of an irrigation water source is the most important short-term and long-term predictor of farm productivity, as measured by the yield potential of crops irrigated with that water. The most common indicator of salinity is total dissolved solids (TDS). Another indicator, favored by agronomists and field practitioners is the EC of the water, since it is linearly proportional to the concentration of inorganic compounds present in the water.

## IMPACT OF SALINITY ON CROP YIELD

Yield reductions occur when salts accumulate in the plant root zone, thus increasing its osmotic pressure. If the increase in salinity is to such an extent that the crop is no longer able to extract sufficient water from the salty soil solution, water stress occurs in plant tissues for a significant period of time—a condition termed physiological drought, since the symptoms are identical with those resulting from a prolonged lack of water. If water uptake is thus appreciably reduced, the plant slows its rate of growth and crop yield is proportionately reduced, as discussed in more detail below, under the heading "Salt Impact on Crop Yield".

## SALT CONTENT OF SOURCE WATERS

The anticipated monthly flows of various source waters into the RTP were used to compute predicted salinity concentrations in the blended recycled water under various scenarios. The blend ratios of the various water sources are shown in tabular and graphic forms in Appendix A.

The source waters and their average salinities are shown in Table 2 based on the Source Water Analysis prepared for the proposed project dated October 17, 2014 by the Monterey Peninsula Water Management District. The last column in the table is the most likely salinity of the water at equilibrium in the root zone, relevant to each source water if used independently for irrigation (which is not the case for the proposed project). This value, known in soil science terminology as ECe (electrical conductivity of the soil saturated paste extract), would be the salinity experienced at the root zone by plant roots. Crop tolerance and yield potential are related to this parameter.

*Table 2 Salinity of Source Waters and Long-Term Root Zone Soil Water*

| Source of Water | Salinity, TDS[1] (mg/L) | Salinity, ECw (dS/m) | Likely Root Zone Salinity, ECe (dS/m) |
|---|---|---|---|
| Municipal Wastewater | 793 | 1.44 | 2.88 |
| Agricultural Wash Water | 820 | 1.59 | 3.18 |
| Blanco Drain | 2003 | 2.84 | 5.68 |
| Lake El Estero | 1226 | 2.56 | 5.12 |
| Tembladero Slough | 1963 | 2.94 | 5.88 |
| Reclamation Ditch | 641 | 1.17 | 2.34 |

1. Source of salinity data: Williams, 2014.

When the build-up of soluble salts in the soil becomes or is expected to become excessive, the salts can be leached by applying more water than is needed by the crop during the growing season. This extra water moves at least a portion of the salts below the root zone by deep percolation (leaching). Leaching is the key factor in controlling soluble salts brought in by the irrigation water. Over time, salt removal by leaching must equal or exceed the salt additions from the applied water or salts will build up and eventually reach damaging concentrations. The terms "leaching fraction (LF)" and "leaching requirement (LR)" are used interchangeably. They both refer to that portion of the irrigation water that should pass through the root zone to control salts at a specific level. While LF indicates that the value be expressed as a fraction, LR can be expressed either as a fraction or percentage of irrigation water.

ECe is a function of the applied irrigation water salinity (ECw) and the LR. Because variations in existing irrigation management practices among farmers are too great to generalize, a conservative 10 to 15% LR is assumed in translating the ECw to the salinity in the root zone (ECe). According to Grattan (2002), the relationship between ECw, LR, and ECe is as follows:

**LR at 10% leads to ECw x 2.1 = ECe**
**LR at 15-20% leads to ECw x 1.5 = ECe**
**LR at 30% leads to ECw ~ ECe**

For the purposes of this analysis, it is estimated (conservatively) that the **ECw x 2.0 = ECe**. This estimate is consistent with field observations in the CSIP service area over a ten-year period (Platts, 2014A).

Both sets of data (TDS and EC) for all source waters are presented in Table 2, in addition to the anticipated salinity in the root zone, under long-term irrigation equilibrium with moderate leaching fraction of 15% to 20%.

**SALINITY—TDS or EC?**

The data used in this TM for calculating the predicted impact of salinity on crop yield are derived from average measurements of electrical conductivity on the various source waters involved. The salinity of those same source waters is also often reported as total dissolved solids. While this parameter was not used in the impact analysis, it is important to note that it is directly related to EC. The linear relationship between EC and TDS is a function of the specific mix of cations, anions, and other compounds in the water.

According to the soil science/agronomy literature, the generalized conversion factor for salinity, from TDS to EC, is:

**TDS in mg/L = 640 x EC in dS/m**
(Grattan, 2002)

Salinity measurements on water samples from Reclamation Ditch and Blanco Drain appear to follow this equation. However, actual measurements of both TDS and EC on samples of recycled water from the RTP, over the last several years, lead to a different conversion factor:

**TDS in mg/L = 550 x EC in dS/m**

The agricultural wash water and Lake Estero water samples also appear to follow this equation. Because of the availability of actual data for some of the source waters, the latter conversion factor is preferred for converting salinity units from TDS to an equivalent electrical conductivity value.

## SALINITY OF BLENDED WATER

Blended recycled water will have a different composition every month and under various phases and scenarios. The projected operational scenarios are described in the textbox to the right.

While Table 2 indicates that most of the new source water salinities are significantly higher than the salinity of the existing RTP recycled water, it is important to understand what the predicted blend salinity will be based on the actual composition of blends of the different source waters that will be combined with wastewater and treated to produce future recycled water (Holden, Sterbenz 2014).

The composition of blends during each month of the year, under various scenarios is provided in Appendix A. The most critical blend (flows of various sources under the drought scenario) is graphically presented in Appendix A, Figure A-1.

A detailed analysis of potential maximum salinity of the blended water sources under various scenarios was performed by Trussell Technologies, Inc. (Williams, 2014). Based on that analysis, the salinity of recycled water during the highest-salinity month for each scenario is depicted in Figure 2.

**PROJECT PHASES AND OPERATIONAL SCENARIOS**

**Phase A:** includes administrative permit applications to the State Water Resources Control Board for diverting less than 3 cubic feet per second (cfs) and less than 200 acre-feet per year (AFY) of storage of surface water from the Reclamation Ditch at Davis Road, Tembladero Slough at Castroville, and Blanco Drain.

**Phase B:** includes an application to the State Water Resources Control Board (SWRCB) to increase diversions to up to 6 cfs each from the Reclamation Ditch at Davis Road and from Blanco Drain.

**Normal Rain–Wet; Building Reserve:** Under this scenario, during normal and above-normal rainfall, only the most favorable water sources—in terms of water quality—would be utilized, avoiding the high-salinity sources (Tembladero Slough and Blanco Drain). During such periods, the system would be producing extra water to store in the ground as a “water bank”, which is 200 AFY, up to a total storage of no more than 1,000 acre-feet (AY).

**Normal Rain–Wet; Full Reserve:** This scenario pertains when the banked maximum 1,000 AF of storage total has been met and the system is not producing extra water for storage

**Drought:** Under drought conditions, water is still withdrawn from the Seaside Groundwater Basin by California American Water (i.e., water previously banked). In these scenarios, additional source waters are provided after secondary treatment to the Salinas Valley Reclamation Plant for recycling and crop irrigation, in lieu of advanced treatment for Seaside Groundwater Basin injection.

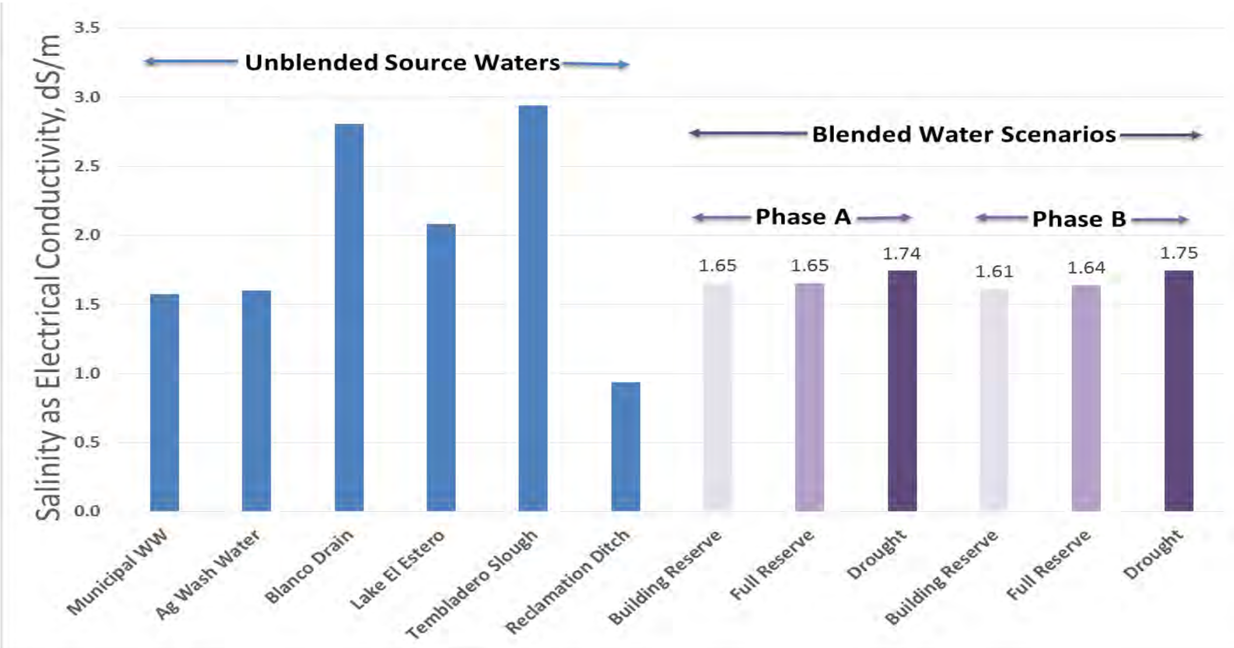

***Figure 2  Highest Monthly Salinity in Source Water Blends under Various Scenarios***

## SALT IMPACT ON CROP YIELD

The classic salinity/yield relationship was described by Shannon (1997) in a graphic reproduced below as Figure 3.

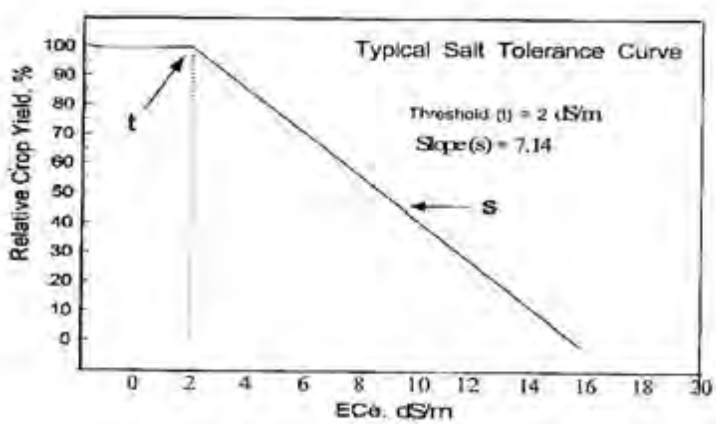

***Figure 3  Relative Crop Yield (% of maximum potential) As a Function of Root Zone Salinity (ECe)***

According to this model, there is a salinity threshold for each crop below which 100% yield can be obtained, assuming that there are no other limitations. Beyond that threshold, increasing salinities result in decreasing yields. For each crop, there is a different rate at which this decline takes place. For salt-tolerant crops, the threshold occurs at higher ECe and the slope is shallower. For salt-sensitive crops, the threshold occurs at lower ECe and the slope is much steeper.

## CROPS GROWN IN CSIP SERVICE AREA

The typical crops grown with recycled water in the CSIP service area are presented in Table 3.

***Table 3 Crops Commonly Grown in the CSIP Service Area and their Salinity-Yield Threshold[1]***

| Crop | Acres | Percentage of US Acreage [2] | Threshold Salinity as ECe (dS/m) |
|---|---|---|---|
| Artichoke | 4,000 | 76 | 6.1 |
| Lettuce | 4,000 | 1.8 | 1.3 |
| Cauliflower | 2,000 | 4.8 | 2.8 |
| Broccoli | 800 | 1.1 | 2.8 |
| Strawberries | 1,650 | 2.3 | 1.0 |
| Celery | 270 | 1.0 | 2.4 |

1. Source for crop acreage: Holden, 2015 and 2005; Source for threshold salinity: Shannon, 1997
2. The percent of United States acreage may be inaccurate because of the ten-year age of the data, while acreages for the CSIP service area are estimates for current conditions.

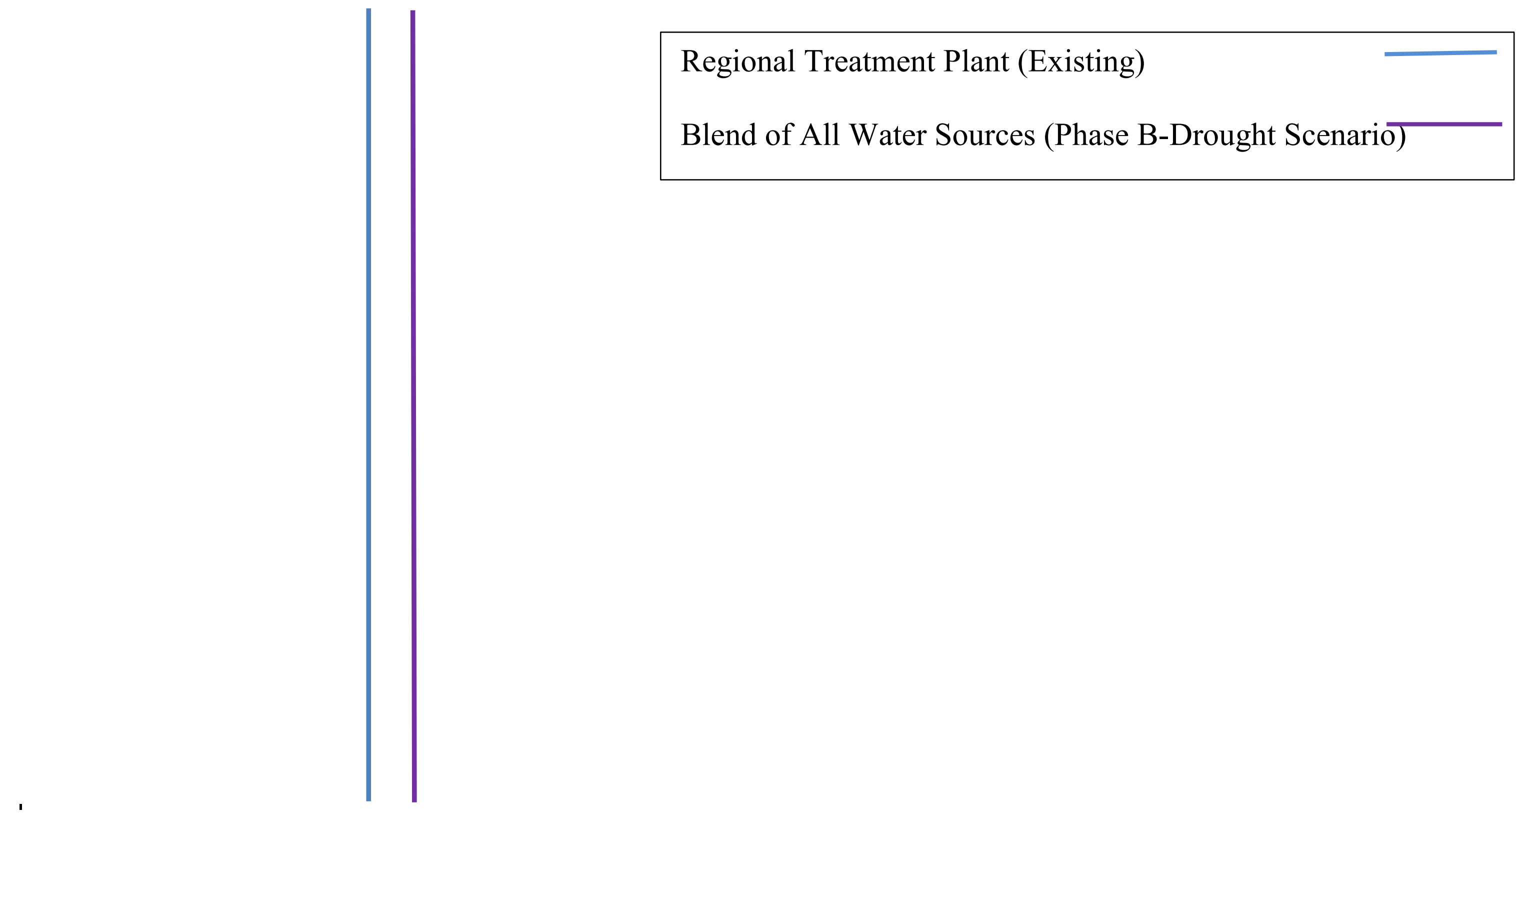
## YIELD REDUCTION UNDER DIFFERENT BLEND SCENARIOS

Salinity and yield are related based on extensive field experiments at agricultural research stations managed by the University of California Agricultural Extension Service. The baseline for these graphics is an ideal growing environment where crop yield is not restricted by any environmental or artificial limitations. Under those conditions, the yield of a given crop is pegged as its 100% potential yield. Keeping all other environmental and artificial conditions constant and varying only the soil water salinity over a series of experimental plots produces the graphics similar to those on Figures 3, 4, and 5. These graphics have been published in textbooks, monographs and periodicals (Shannon, 1997, Grattan, 2002, and others).

For the purposes of this TM, the graphical representations from Shannon (1997) are reproduced in Figures 4, 5, and 6 below. Each graphic is annotated with the equilibrium root zone soil water salinities resulting from irrigation with the two recycled waters in the scenarios under discussion:

(1) the existing RTP recycled water, potentially resulting in soil water salinity of **2.88 dS/m** (1.44 x 2 = 2.88)

(2) maximum salinity in Phase B drought condition, potentially resulting in soil water salinity of **3.50 dS/m** (1.75 x 2 = 3.50)



Source: Shannon, 1997

*Figure 4 Relative Yield of Lettuce, Broccoli, and Cabbage at two Root Zone Salinities*

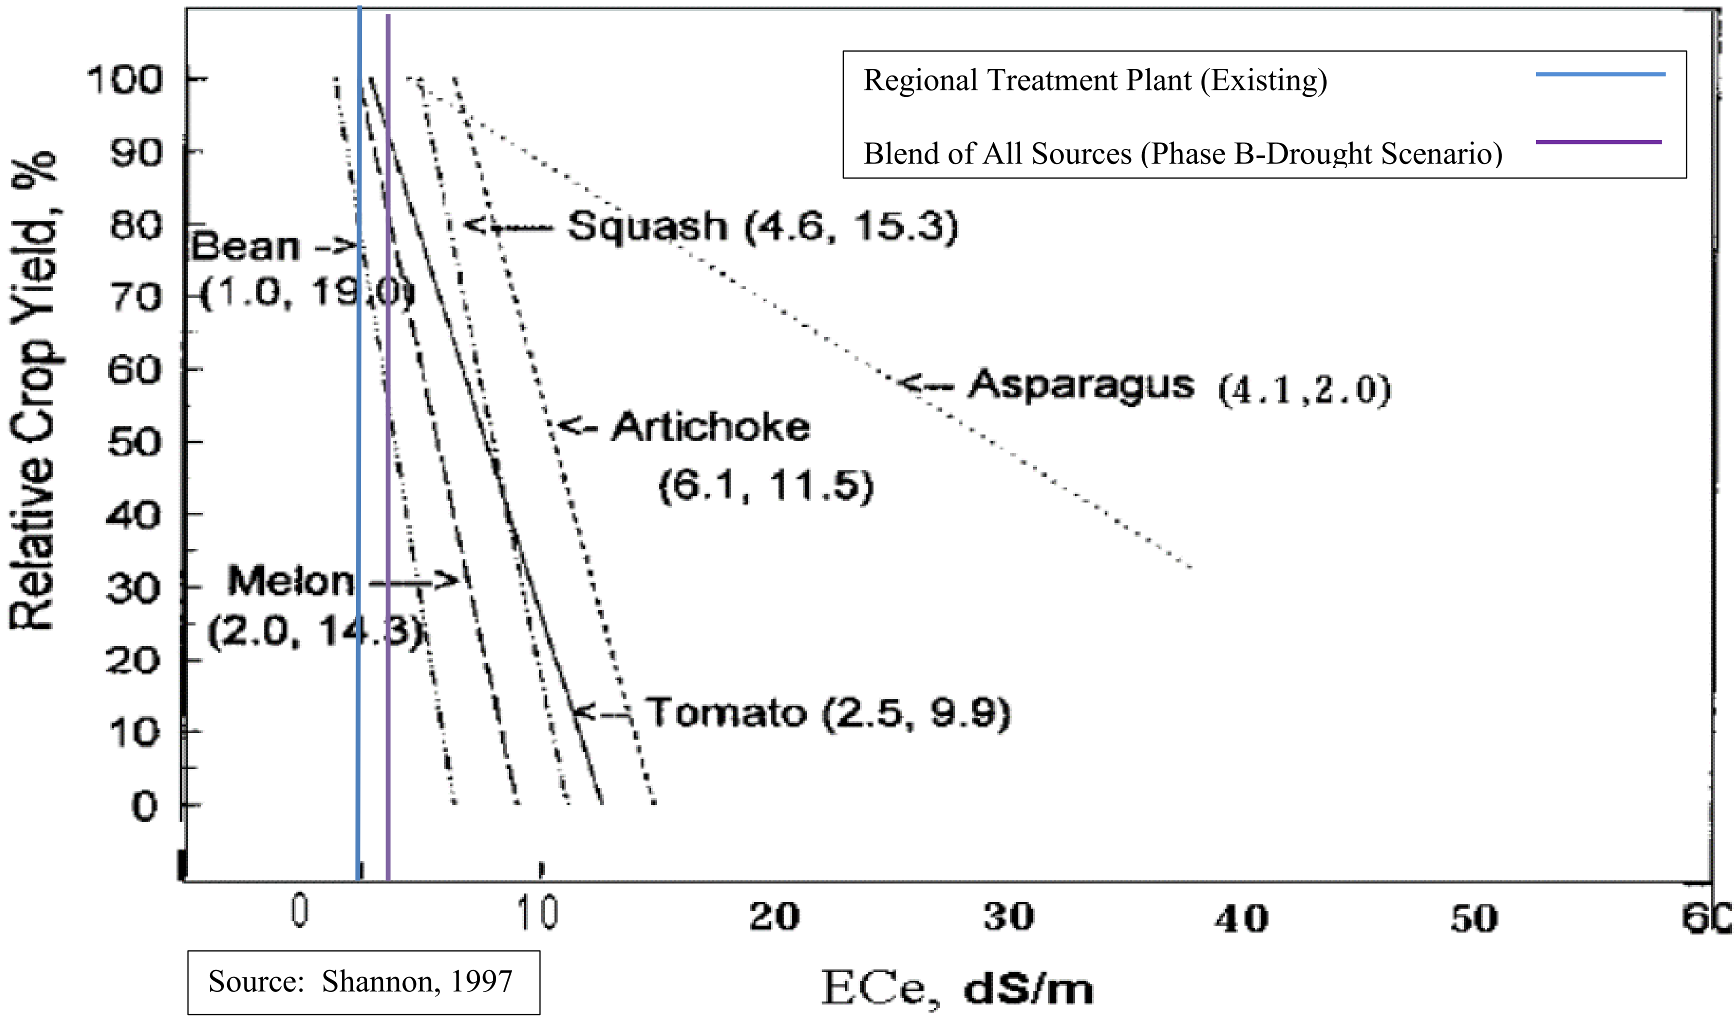


***Figure 5 Relative Yield of Artichoke at two Root Zone Salinities***

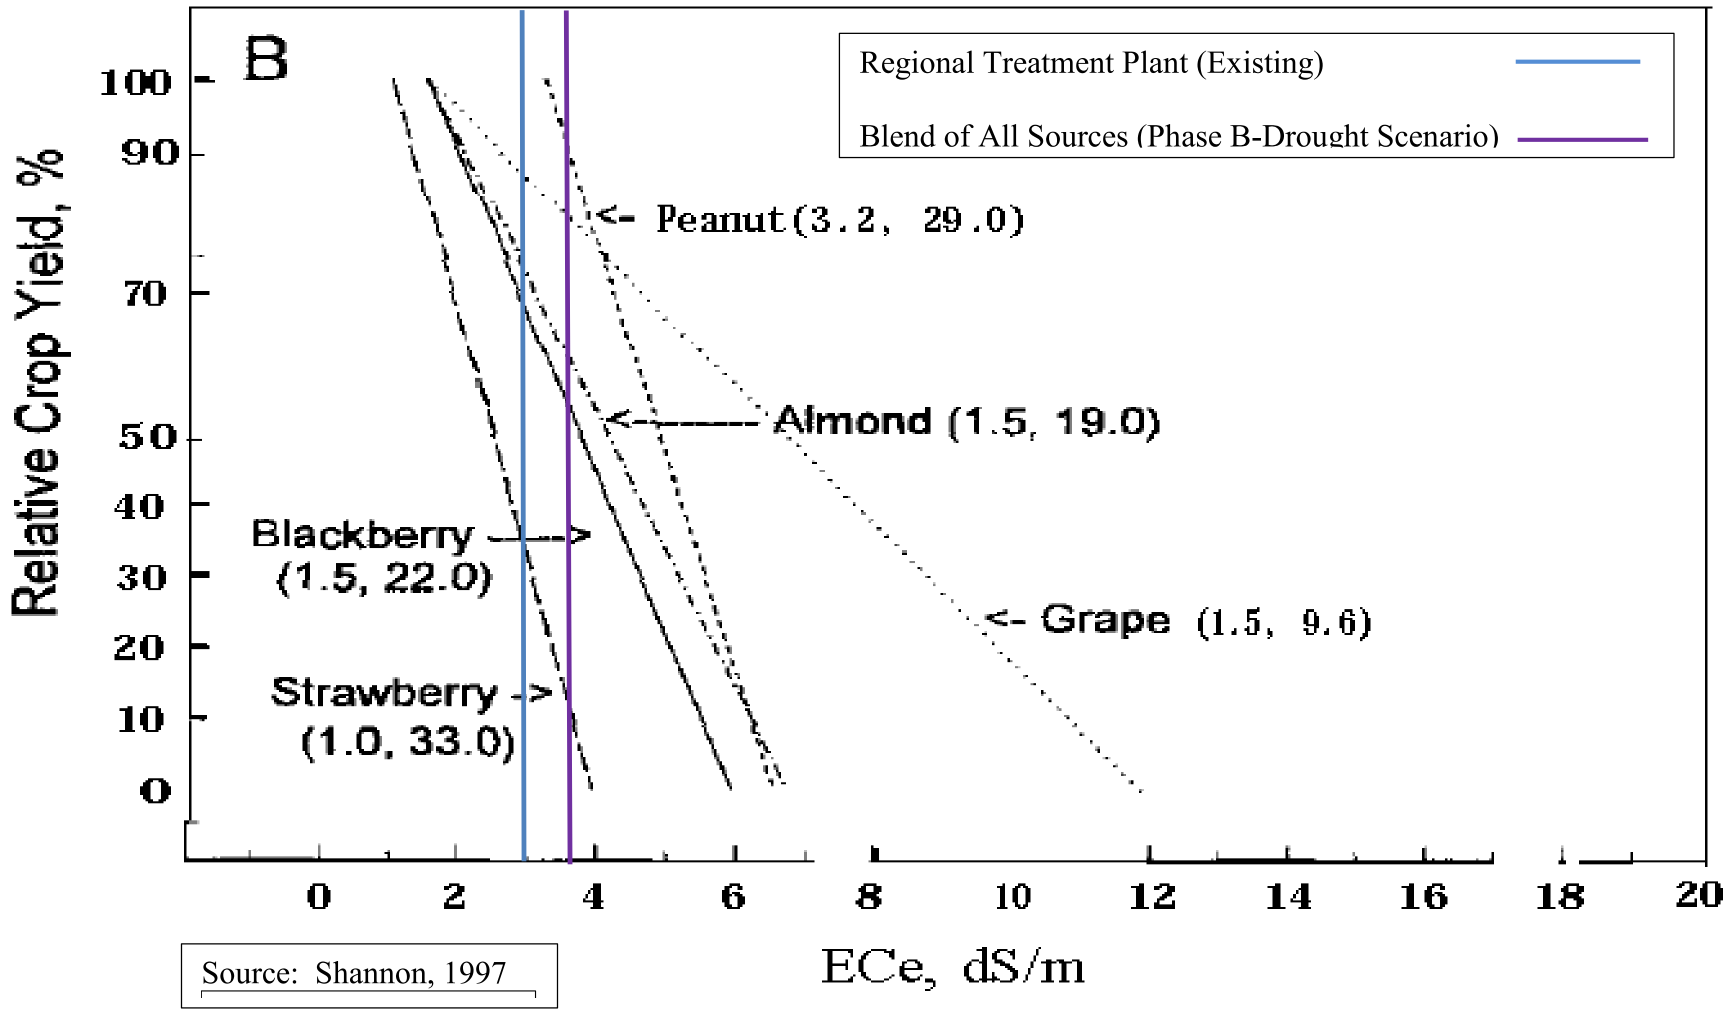

*Figure 6 Relative Yield of Strawberry at two Root Zone Salinities*

Intersection points of each soil water salinity (ECe) with the corresponding crop's yield graph provides the estimated percent yield potential resulting from long-term use of recycled water associated with that average salinity value. The results are summarized in Table 4.

***Table 4 Estimated Crop Yield, as Percentage of Maximum Potential Yield, with Two Recycled Water Salinity Scenarios***

| Crop | Yield with Existing RTP Water, ECe = 2.88 (dS/m) | Yield with Blend of All Source Waters, without River Water ECe = 3.5 (dS/m) | Yield Impact, % |
|---|---|---|---|
| Artichoke | 100% | 100% | 0 |
| Lettuce | 80% | 73% | -7% |
| Cauliflower | 100% | 95% | -5% |
| Broccoli | 100% | 95% | -5% |
| Strawberries | 35% | 15% | -20% |
| Celery | 95% | 85% | -10% |

## PREDICTED ECONOMIC IMPACT OF YIELD REDUCTION

Subtracting percent yield obtained for each crop irrigated with the blend of source waters from the yield of that same crop irrigated with the existing RTP recycled water gives percent yield reduction for each crop as shown in the first column of Table 5. Extending the percentage yield reduction to the acreage and value of each crop provides the estimated maximum annual loss of value that would result from use of all source water blends as irrigation water.

As discussed previously, this maximum annual loss is provided for the worst-case scenario of source water diversions in a drought year without dilution with river water or implementation of any salinity management measures by farmers. The next section describes the measures that have been used in the past, and that can be used in the future by farmers to safely and profitably irrigate the land and avoid these potential losses.

**Table 5 Estimated Yield Reduction for Each Crop Irrigated with Source Waters**

| Crop | Maximum Yield Decrease Due to Use of Blend with All Source Waters | Annual Value of Crop[1] $/Acre | Total Value of Crop In CSIP Area[2] $/Year | Loss of Value Due to Use of Blend of All Source Waters $/Year |
|---|---|---|---|---|
| Artichoke | 0% | 9,108 | 36,433,000 | 0 |
| Lettuce | -7% | 11,034 | 44,135,000 | -3,089,000 |
| Cauliflower | -5% | 7,782 | 15,564,000 | -778,000 |
| Broccoli | -5% | 6,510 | 5,208,000 | -260,000 |
| Strawberries | -20% | 79,188 | 130,661,000 | -26,132,000 |
| Celery | -10% | 16,024 | 4,327,000 | -433,000 |
| Total: | | | **236,328,000** | -30,692,000 |
| Percent Loss: | | | | -13% |

1. Annual crop values were obtained from Monterey County Office of Agricultural Commissioner's 2013 Crop Reports (MCAC, 2014), by dividing the County-wide value of each crop by the acreage in which the crop was produced in that year.
2. Total value of each crop was calculated by multiplying the annual value of the crop by the estimated acreage of the crop in the CSIP service area, shown in Table 3.

## DISCUSSION

The estimated losses of crop production value shown in Table 5 are based on simple theoretical relationships and can only be realized if the growers do nothing in response to the elevated level of salinity. Strong evidence for the ability of the currently produced recycled water to provide a safe and profitable irrigation resource has been obtained from previous research:

### Monterey Wastewater Reclamation Study for Agriculture

Prior to large-scale use of recycled water in the CSIP area, a five-year field pilot project was undertaken to determine the potential impact of using recycled water for irrigation of food crops, its safety, and the potential for marketing the produce. The results of that research project, in which recycled water from the now-demolished Castroville wastewater treatment plant was used, have been published (Sheikh et al., 1998). The results provided evidence, over a five-year period, that

- soil permeability, as measured in the field on plots irrigated with recycled water and those irrigated with well water were not significantly different,
- crop yields were equal to or higher than those irrigated with well water, and
- quality and shelf-life of the crops were not significantly different from those grown with well water.

### Soil Salinity Monitoring in CSIP Area

A monitoring study of soil characteristics has been underway at several test sites and control sites to track changes attributable to long-term use of recycled water in the CSIP service area. Some of the results were recently published in California Agriculture (Platts 2014A, 2014B). While some trends in increasing levels of EC, sodium, chloride, and SAR were noted, above control levels, the critical role of annual precipitation in diluting and removing accumulated salts was also observed. Overall, it was concluded that

> "In 13 years of data, the average soil salinity parameters at each site were highly correlated with the average water quality values of the recycled water. Soil salinity did increase, though not deleteriously. Of most concern was the accumulation of chloride at four of the sites, to levels above the critical threshold values for chloride-sensitive crops."

Another conclusion from this research is that

> "Increasing rainfall depths were significantly correlated with decreasing soil salinity of the shallow soil at all test sites, though this effect also diminished with increased soil depth. When applied water had high salinity levels, winter rainfall in this area was inadequate to prevent soil salinity from increasing."

Several types of management strategies are in use for salinity control and would be used to prevent any theoretically calculated reductions in yield. These strategies are listed below:

### Blending with Salinas River Water

Recycled water currently is blended with Salinas River water during most parts of the year and in most years, except following the driest winters, before delivery to the farmers. This practice is expected to continue in the future. Therefore, few if any of the framers will be irrigating at all times with a straight blend of recycled water from the sources indicated above. Salinas River water has a much lower salinity than any of the source waters discussed here (except the storm water). Of the new source waters to be used for the proposed project, Agricultural Wash Water will be highest volumetric contributor and has higher EC values than those in the current recycled water. Thus, timing of the Agricultural Wash Water contribution to the RTP is important when understanding the effects of blending recycled water with Salinas River water. Significantly, the greatest extent of blending with Salinas River water and recycled water containing Agricultural Wash Water is expected to occur during the peak summer period when plants would be growing at the highest rate and would benefit the most from a reduced salinity level. The beneficial, counteracting impact of the Salinas River water cannot be readily quantified because of the variable and temporal rates at which it will be introduced as influent to the irrigation system. If the CSIP service area is expanded in the future, more Salinas River water will be required to be blended to meet the demand. This will further dilute the salt content of the blended recycled water from all sources.

### Agronomic Management Practices

Growers in Salinas Valley are some of the most sophisticated and technologically advanced farmers in the world. They will, in all likelihood, respond to a higher salinity blend of recycled water by employing agronomic management practices, including the following: regular monitoring using sensors; increasing the leaching fraction; modifying irrigation scheduling; leaching during the cool seasons to improve leaching efficiency; scheduling leachings at periods of low crop water use or postponing leachings until after the cropping season; land leveling for better water distribution; installing additional tile drains to improve leaching, scheduling timing of irrigations to prevent crusting and water stress; placement of seed to avoid areas likely to be salinized; careful selection of materials, rate and placement of fertilizers; and addition of agricultural amendments, as needed.

### Salt Tolerant Varietals

California's academic institutions and agricultural research services are continuing research in plant breeding for salt tolerance, higher yields, and more consumer-attractive characteristics. These efforts routinely produce varietals and cultivars that, among other beneficial traits, can tolerate higher salt levels in the soil root zone, producing near maximum potential yield. In particular, the strawberries grown in the CSIP service area are patented proprietary varietals adapted to the conditions and water quality at hand.

### Trends for Crops Grown in the CSIP Service Area

Even though the calculations in this TM indicate a significant yield reduction for strawberries grown with the RTP recycled water, actual field experience of the farmers does not bear this out. In fact, over the period of recycled water delivery, much of the farmland in the CSIP service area has been shifted from growing artichoke (a salt-tolerant plant) to producing strawberries (a salt-sensitive crop), as shown in Table 6. This shift indicates that the farmers are obtaining adequate (possibly superior) yields and high-quality harvests from their investment, under the recycled water irrigation regime.

***Table 6 Shifts in Crop Acreage and Corresponding Value[1] from Artichokes to Strawberries in CSIP Service Area***

| Crop | | 1998 | 2010-2014[2] | Change |
|---|---|---|---|---|
| Artichokes | Acres | 4,200 | 3,900 | -7% |
| | Dollars | 25,262,000 | 35,522,000 | 41% |
| Strawberries | Acres | 120 | 1,642 | 1,300% |
| | Dollars | 3,641,000 | 130,027,000 | 3,500% |

1. Crop values were obtained from Monterey County Office of Agricultural Commissioner's 2013 Crop Reports (MCAC, 2014). Crop acreages were provided by Bob Holden, MRWPCA.
2. Artichoke acreage is for 2010; strawberry acreage is for 2014.

## CONCLUSION

The addition of new source waters for the proposed project is likely to increase the recycled water salinity above that currently produced at the RTP. This change in water quality is not expected to impact the farming activities within the CSIP service area to a significant extent, mainly because of the various management tools and expertise available to the growers, some of which are already in practice. It is estimated that the increased salinity of the recycled water resulting from the blend of existing raw wastewater with the new source waters may result in a 13% reduction in total crop production value in the CSIP service area during a drought year scenario only under two conditions (1) if Salinas River water is not available for dilution and (2) if salinity control crop management practices are not implemented to maintain yield. In practice, the potential loss of crop value would be ameliorated by the implementation of standard strategies and management practices to address higher salinity levels in irrigation water sources.

The farming enterprise is a dynamic industry with constant revision of policies, practices and procedures to meet changing environmental and input variables, including irrigation water quality. Over the 17-year period of using recycled water for irrigation in the CSIP service area, large tracts of salt-tolerant artichoke have been converted to growing salt-sensitive, but far more profitable, strawberries. This conversion attests to the ingenuity of local growers and their ability and willingness to adapt real-time to water quality variations and economic realities.

# TECHNICAL MEMORANDUM

**DATE:** November 10, 2014

**TO:** Robert Holden
Monterey Regional Water Pollution Control Agency (MRWPCA)

**FROM:** Gang Zhao, Ph.D., P.E., Aaron Mead, P.E., E. John List, Ph.D., P.E.

**SUBJECT:** **MRWPCA GWR Discharge Dilution Analysis**
**FSI 144082**

## 1. Introduction

As part of the preparation process for the Monterey Peninsula Groundwater Replenishment Project (GWR Project), Flow Science Incorporated (Flow Science) was retained by Monterey Regional Water Pollution Control Agency (MRWPCA) to analyze characteristics of the plume resulting from the discharge of effluent (comprised of secondary effluent from the Regional Treatment Plant (RTP), truck hauled brine, and brine concentrate produced by the Advanced Water Treatment Facility (AWTF) for the proposed Pure Water Monterey Groundwater Replenishment Project (GWR Project)) through the existing MRWPCA ocean outfall.

In October 2014, Flow Science performed a dilution analysis of the proposed GWR Project effluent for six (6) selected discharge scenarios, as summarized in **Table 1**. These scenarios were selected based on the results of a dilution analysis for fourteen (14) prescreening scenarios, as listed in **Appendix C**. Scenarios in **Appendix C** were selected to cover a wide range of discharge conditions, and to provide preliminary knowledge of the various factors affecting dilution of the effluent. For each scenario in **Table 1**, temperature of the combined flow was assumed to be 20 °C, and effluent dilution was analyzed for three seasonal conditions: Davidson (January), Upwelling (July) and Oceanic (September). Zero ocean current was used for all scenarios consistent with the California Ocean Plan (State Water Resources Control Board, SWRCB, 2012).

**Table 1 – Diffuser scenarios modeled**

| Scenario | Flow Assumptions (mgd) | | | | TDS Assumptions (mg/L) | | | |
|---|---|---|---|---|---|---|---|---|
| | Wastewater | Hauled Brine | GWR Brine | Total Flow | Wastewater | Hauled Brine | GWR brine | Combined |
| 1 | 0.2 | 0.1 | 0.94 | 1.24 | 1100 | 40,000 | 5,800 | 7800 |
| 2 | 0.4 | 0.1 | 0.94 | 1.44 | 1100 | 40,000 | 5,800 | 6869 |
| 3 | 0.6 | 0.1 | 0.94 | 1.64 | 1100 | 40,000 | 5,800 | 6166 |
| 4 | 0.8 | 0.1 | 0.94 | 1.84 | 1100 | 40,000 | 5,800 | 5615 |
| 5 | 1.0 | 0.1 | 0.94 | 2.04 | 1100 | 40,000 | 5,800 | 5173 |
| 6 | 1.2 | 0.1 | 0.94 | 2.24 | 1100 | 40,000 | 5,800 | 4809 |

mgd = million gallons per day, mg/L = milligrams per liter, TDS = total dissolved solids.

This Technical Memorandum (TM) summarizes the analysis Flow Science completed for the scenarios presented in **Table 1** and describes the input data, methods and results of Flow Science's analysis.

## 2. Analysis Input Data

### Diffuser Configuration

The existing MRWPCA diffuser has 172 ports. Half of the ports discharge horizontally from one side of the diffuser and half discharge horizontally from the other side of the diffuser in an alternating pattern. Since Visual Plumes, the model used to analyze effluent dilution in this analysis, does not have the capability to model ports on alternating sides of a diffuser, all ports were modeled to be on one side of the diffuser. This assumption leads to conservative model results because the plumes from individual ports overlap more quickly under modeled conditions than in reality, and so modeled effluent dilutions are somewhat lower than would be reflected in reality.

According to MRWPCA, the fifty-two (52) ports nearest to the shore (i.e., the shallowest ports) are currently closed. In this analysis, Flow Science calculated dilution of effluent discharged through the 120 open ports for Scenarios 1 through 6. A typical section of the current diffuser is shown in **Figure 1**, although the actual cross-sectional profile of the pipe ballast may have changed over time. The ports are approximately 6 inches above the rock bedding of the diffuser pipeline, and drawings[1] (see **Figure 1**) indicate that they are located approximately 3.9 feet above the seafloor[2]. The gravel bedding dimensions are nominal, as shown in **Figure 1**, and therefore, the port height above the seafloor is not known with high accuracy. Momentum and buoyancy of the effluent are the key factors in determining the dilution within the zone of initial dilution (ZID). Toward the end of the ZID, the plume slows down and mixing is not as strong as at the beginning of the ZID. Therefore, the dilution results are not likely to change by much if the port height is not precisely known and, considering the overall uncertainty in the analysis, it is not critical to determine the diffuser port height with high accuracy. In this analysis, it was assumed that effluent plumes do not interact with the ballast, which is supported by the plume dimensions computed. Details of the current diffuser configuration are summarized in **Table 2**.

**Table 2 – Current diffuser configuration.**

| Parameter | Value |
|---|---|
| Diffuser length | 1368 feet (417 m) |
| Depth of diffuser ports | 95 to 109 feet below MSL |
| Number of open ports | 120 |
| Port spacing | 8 feet (2.44 m) |
| Port diameter | 2 inches (0.051 m) |
| Port exit condition | Tideflex Series 35 4-inch duckbill valves |
| Port vertical angle | $0^{\circ}$ (horizontal) |
| Port elevation above sea floor | 3.9 feet (1.19 m) |

m = meters, MSL = mean sea level

[1] Section F, Drawing P-0.03, Contract Documents Volume 1 of 1: Ocean Outfall Contract No. 2.1, January 1982 by Engineering Science for MRWPCA.
[2] The 3.9 feet (ft) above seafloor used in this analysis is slightly higher than the 3.5 ft used in previous analyses for the desalination brine because the thickness of the pipe wall (about 5 inches) is included. All effluent plumes in this analysis are positively buoyant, and therefore, this change has no impact on the results of this analysis.

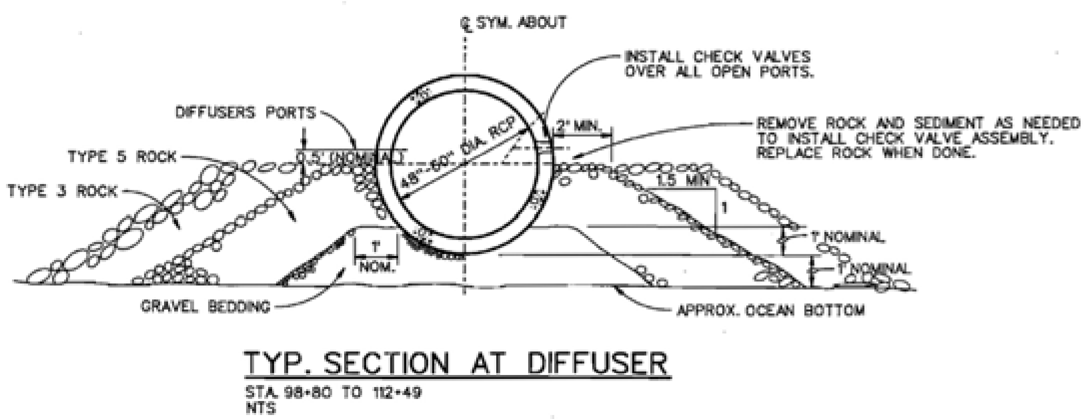

**Figure 1. Typical diffuser section (currently in place).**

The 120 ports that are currently open are fitted with Tideflex "duckbill" check valves, as shown in **Figure 2**. The shape of the duckbill valve opening is elliptic and the area of the opening depends on the discharge flow rate. The valve opening area in this analysis was determined from an effective open area curve provided by Tideflex Technologies (included as **Appendix A**). Although the ports were modeled as round openings with the same opening area as the "duckbill" valves, because of the oblateness of the actual port opening, the actual dilution will be slightly higher than the dilution computed assuming circular ports. This is because the perimeter of ellipse, which is where the entrainment of diluting water occurs, is larger than that of a circle having the same area.

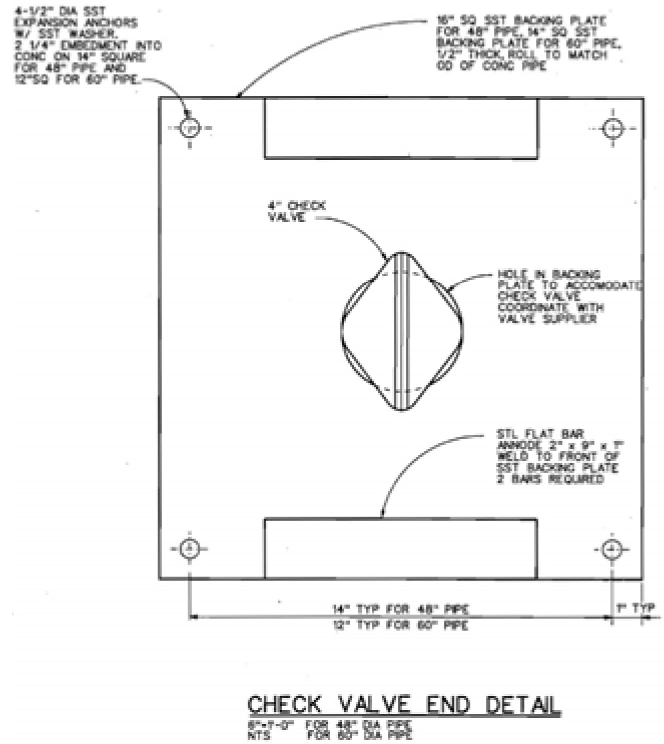

**Figure 2. Typical "duckbill" valve detail (shown closed, i.e., with no flow).**

## Discharge Characteristics

Total Dissolved Solids (TDS) and temperature data for the proposed GWR Project brine concentrate, hauled brine and the MRWPCA wastewater have been compiled and provided by Trussell Technologies, Inc. (Trussell Tech). TDS is a measure of water salinity, and salinity and temperature are used to calculate the density of the effluent and ambient ocean water, which are important parameters in dilution analyses.

Discharge rate, temperature, and TDS data, provided by Trussell Tech and presented in **Table 3**, were used in the analysis for all three seasonal conditions. For the combined proposed GWR Project brine concentrate, trucked brine, and wastewater flow scenarios, the concentrate was assumed to be fully mixed with the wastewater. Thus, the temperature and TDS of the combined flow were calculated as the flow-weighted average temperature and salinity of the brine and wastewater.

All scenarios summarized in **Table 3** were analyzed for zero ocean current velocity conditions, which represent worst-case conditions since any ocean current only increases dilution. Ocean currents increase the amount of dilution that occurs because they increase the flow of ambient water past the diffuser (i.e., increase the amount of ambient water available for mixing with the discharge). Although ocean currents increase effluent dilution, the California Ocean Plan (State Water Resources Control Board, SWRCB, 2012) requires that the no-current condition should be used in initial dilution calculations.

**Table 3 – Summary of input for analyzed scenarios.**

| Scenario | Combined Flow (mgd) | Combined TDS (mg/L) | Combined Temp. ($^oC$) | Number of Diffuser Ports | Effective Port Diameter (inches) |
|---|---|---|---|---|---|
| 1 | 1.24 | 7800 | 20 | 120 | 0.93 |
| 2 | 1.44 | 6869 | 20 | 120 | 0.97 |
| 3 | 1.64 | 6166 | 20 | 120 | 1.01 |
| 4 | 1.84 | 5615 | 20 | 120 | 1.05 |
| 5 | 2.04 | 5173 | 20 | 120 | 1.09 |
| 6 | 2.24 | 4809 | 20 | 120 | 1.12 |

**Receiving Water Profiles**

Representative ocean receiving water profile data (temperature and salinity) for the three months corresponding to the selected seasonal conditions (July, January, and September) used in a previous dilution study (Flow Science, 2014) for the proposed Monterey Peninsula Water Supply Project Desalination Plant were also used in this analysis. Receiving water profile data were collected by the Monterey Bay Aquarium Research Institute (MBARI) at station C1 at the head of Monterey Canyon, approximately five miles northwest of the MRWPCA wastewater ocean outfall (see **Figure 3**). This location has been occupied since 1988 by MBARI. Monthly conductivity, temperature, and depth (CTD) profiles have been collected since 2002. The proximity of the location to the MRWPCA ocean outfall and the long data record make this the most appropriate and useful data set to characterize the ambient conditions for the brine discharge analysis. Vertical profiles of temperature and salinity were analyzed for the upper 50 meters of the water column for the years 2002-2012, and a single representative profile was selected for each of the three ocean seasons. The appropriate profiles were selected based on which were most complete, i.e., which profiles had data for the entire water column (in some cases profiles did not extend over the entire depth of the water column), and to ensure that the profiles represented typical conditions of the seasonal ocean profiles. For the July model run, temperature and salinity profiles from 2011 were selected. For the September model run, profiles from 2004 were selected. For the January model runs, a temperature profile from 2004 and a salinity profile from 2011 were selected. Profile data are shown in tabular form in **Appendix B**. Maximum and minimum values for each profile are shown in **Table 4**.

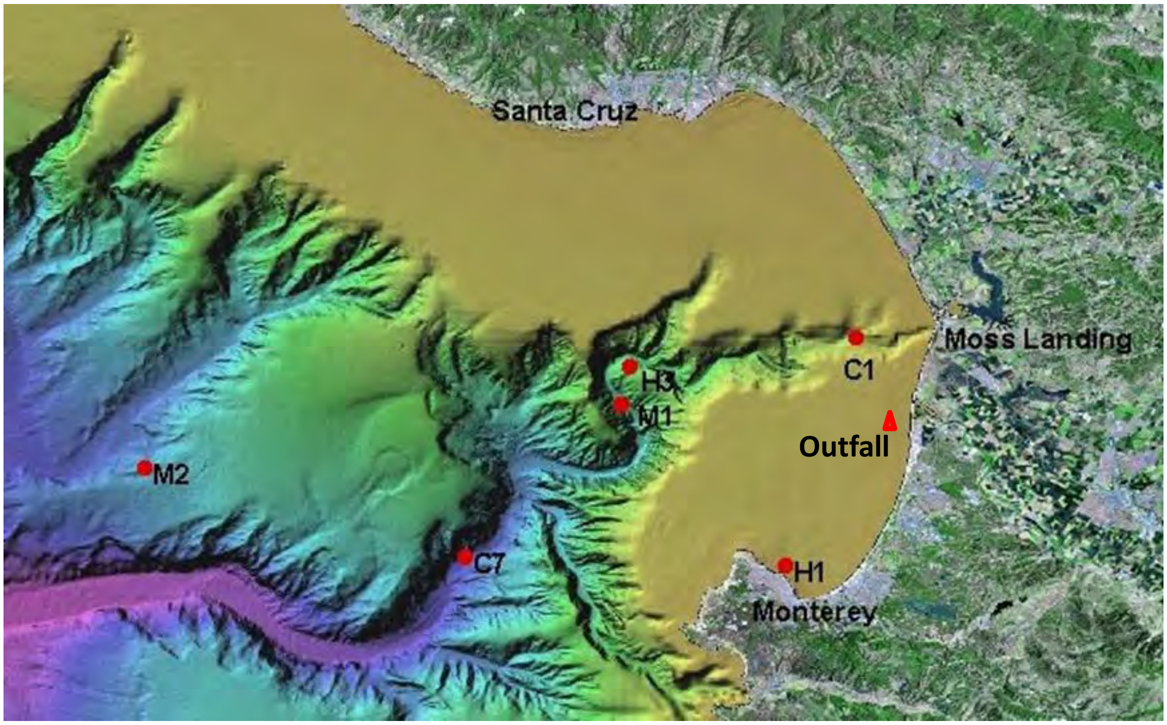

**Figure 3. Location map, MBARI ocean monitoring stations and MRWPCA outfall.**

**Table 4 – Maximum and minimum ocean profile data.**

| Parameter | Season | Minimum | Maximum |
|---|---|---|---|
| Salinity (ppt) | Upwelling (July) | 33.7 | 33.9 |
| | Davidson (January) | 33.2 | 33.5 |
| | Oceanic (September) | 33.5 | 33.6 |
| Temperature ($C^o$) | Upwelling (July) | 10.0 | 13.0 |
| | Davidson (January) | 10.7 | 12.7 |
| | Oceanic (September) | 10.6 | 15.8 |

Source: ESA (2013); Appendix B.

## Receiving water flow conditions

As detailed in **Figure 1**, the existing diffuser ports are located just above the mid-point of the outfall pipe (i.e., below the crown of the outfall pipe), about 6 inches above the top of the ballast used to anchor the diffuser to the seafloor. Because the outfall rises above the seafloor, it will influence the patterns of currents (receiving water flow velocity) at the ports, and the current velocity at each individual port will be a complex function of the local geometry. Local field data collection would be required to characterize the actual current conditions at the diffuser ports, which was beyond the scope and budget of this analysis. To simplify the analysis, effluent dilution was analyzed for a uniform 0.0 foot per second (fps) current, which amounts to a "worst case," stagnant (no current) receiving water condition. Stagnant conditions are typically used as the basis for developing NPDES permits, and the California Ocean Plan (SWRCB, 2012) requires the no-current condition be used in initial dilution calculations.

## 3. Plume Analysis Method

The UM3 model—part of the U.S. Environmental Protection Agency (US EPA) Visual Plumes diffuser modeling package—was used to simulate the discharge of GWR Project effluent and wastewater from the existing MRWPCA ocean diffuser. Visual Plumes is a mixing zone computer model developed from a joint effort led by US EPA. Visual Plumes can simulate both single and merging submerged plumes, and stratified ambient flow can be specified by the user. Visual Plumes can be used to compute the plume dilution, trajectory, diameter, and other plume variables (US EPA, 2003).

The UM3 model is based on the projected area entrainment hypothesis, which assumes ambient fluid is entrained into the plume through areas projected in directions along the plume centerline and perpendicular to the centerline (US EPA, 1994). In addition, shear entrainment is included. The plume envelope is assumed to be in steady state, and as a plume element moves through the envelope, the element radius changes in response to velocity convergence or divergence, and entrainment of ambient fluid. Conservation equations of mass, momentum and energy are used to calculate plume mass and concentrations.

The actual depth of the diffuser ports varies between 95 and 109 feet below mean sea level (MSL) since the diffuser is quite long and is situated on a sloping portion of the ocean floor. However, since Visual Plumes cannot model a sloping diffuser, an average depth of 104 feet below MSL was used for the 120-port scenarios (the deepest 120 ports on the diffuser are assumed to discharge in this case, thereby increasing the average port depth). Modeled ocean conditions are summarized in **Table 5**.

Visual Plumes assumes circular discharge ports, so the actual elliptical discharge area was calculated for each port (**Appendix A**) and then converted to an effective circular discharge diameter for use in Visual Plumes.

**Table 5 – Visual Plumes modeled seasonal ocean conditions.**

| Depth (m) | Upwelling (July) | | Davidson (January) | | Oceanic (September) | |
|---|---|---|---|---|---|---|
| | Temp. ($^oC$) | Salinity (ppt) | Temp. ($^oC$) | Salinity (ppt) | Temp. ($^oC$) | Salinity (ppt) |
| 0 | 12.98 | 33.78 | 12.65 | 33.20 | 15.75 | 33.46 |
| 2 | 12.87 | 33.77 | 12.65 | 33.22 | 15.75 | 33.46 |

Source: Interpolated from ESA | Water (2013) ocean profile data, Appendix B.

The UM3 model was used to calculate the size of the plume and dilution of the discharged effluent within the ZID. The ZID is defined as the zone immediately adjacent to a discharge where momentum and buoyancy-driven mixing produces rapid dilution of the discharge. For a positively buoyant (rising) effluent plume, the ZID ends at the point where the effluent plume reaches the water surface or attains a depth level where the density of the diluted effluent plume becomes the same as the density of ambient water (i.e., the "trap" level). Typically, within the ZID, which is limited in size, constituent concentrations are permitted to exceed water quality standards. A discharge is generally required to meet the relevant water quality standards at the edge of the ZID.

Analysis of the buoyant (rising) plume within and beyond the "trap" level would require additional analysis methods. In the analysis presented here the spreading of the effluent within and beyond the trap level and the subsequent additional dilution that would ensue, has not been analyzed. Flow Science recommends that the computed dilution at the trap level, (i.e., at the end of the ZID), be used as the basis for any NPDES permitting activities and to analyze impacts.

## 4. Dilution Results

Several key results for the effluent plumes are reported at the edge of the ZID. As noted above, the ZID is defined as the zone immediately adjacent to a discharge where momentum and buoyancy-driven mixing produces rapid dilution of the discharge. Results for positively buoyant plumes presented in this Technical Memorandum were taken at the point where the plumes just reached the trap level, which is the depth level where the density of the diluted plume becomes the same as ambient seawater. Horizontal spreading of plumes at their trap levels was not included in this analysis. Results from each scenario generally include the following quantities:

- the minimum dilution of the plume at the point at which the plume reaches the trap level or sea surface;
- an estimate of the size of the plume (diameter) at the trap level or sea surface (i.e., at the edge of the ZID);
- the horizontal distance from the diffuser port to the point at which the plume reaches the trap level or sea surface;
- the height of the trap level above diffuser ports.

**Figure 4** shows a sample schematic graphic of the trajectory of a positively buoyant plume from a horizontal discharge drawn approximately to scale, and the analysis results described in the list above are illustrated. As the effluent travels away from the discharge port, it entrains ambient seawater, which increases the diameter of the plume and decreases the effluent concentration.

**Table 6** presents analysis results for the six (6) modeled scenarios for the selected three seasonal conditions. Effluent plumes are positively buoyant for all analyzed scenarios, and all plumes reach trap levels below sea surface. The calculated minimum dilution value is 218 for all scenarios under all three seasonal conditions.

**Figure 5** illustrates the trajectory and shape of the buoyant plumes just reaching the trap level, as computed from Visual Plumes for Scenario 4. Plumes computed for other scenarios have similar trajectories and shape as shown in the figure.

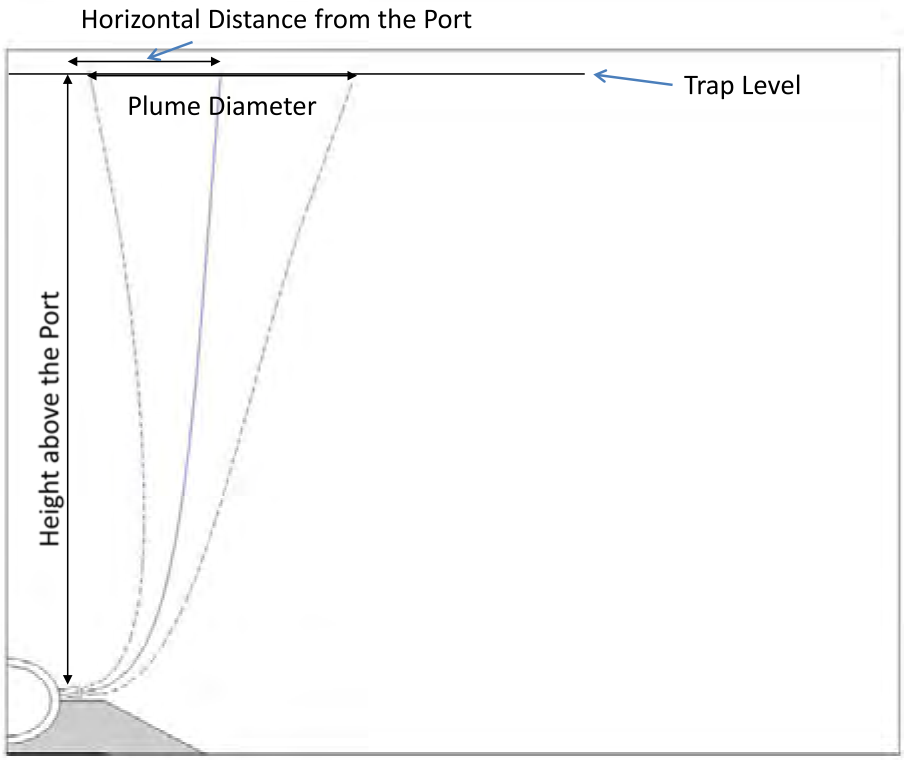

**Figure 4. Sample graphic showing the trajectory of a rising plume.**

FLOW SCIENCE®

**Table 6– Analysis results.**

| Scenario | Total Flow (MGD) | Combined TDS (mg/L) | Number of Open Ports | Davidson (Jan.) | | | | Upwelling (July) | | | | Oceanic (Sept.) | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | | | | Plume Diam. (ft) | Minimum Dilution | Horiz. Distance from Port (ft) | Height above Port (ft) | Plume Diam. (ft) | Minimum Dilution | Horiz. Distance from Port (ft) | Height above Port (ft) | Plume Diam. (ft) | Minimum Dilution | Horiz. Distance from Port (ft) | Height above Port (ft) |
| 1 | 1.24 | 7800 | 120 | 8 | 218 | 6 | 26 | 13 | 541 | 7 | 49 | 11 | 474 | 7 | 42 |
| 2 | 1.44 | 6869 | 120 | 11 | 285 | 7 | 34 | 13 | 512 | 7 | 50 | 11 | 439 | 7 | 43 |
| 3 | 1.64 | 6166 | 120 | 11 | 274 | 7 | 35 | 13 | 483 | 8 | 50 | 11 | 418 | 7 | 43 |
| 4 | 1.84 | 5615 | 120 | 11 | 263 | 8 | 35 | 13 | 453 | 8 | 50 | 11 | 396 | 8 | 44 |
| 5 | 2.04 | 5173 | 120 | 11 | 252 | 8 | 35 | 13 | 440 | 8 | 51 | 11 | 373 | 8 | 44 |
| 6 | 2.24 | 4809 | 120 | 11 | 242 | 8 | 36 | 14 | 426 | 9 | 52 | 11 | 362 | 8 | 45 |

Analysis results are at plume trap levels.

# 1 Introduction

The Monterey Regional Water Pollution Control Agency (MRWPCA) and the Monterey Peninsula Water Management District ("Project Partners") are in the process of developing the Pure Water Monterey Groundwater Replenishment Project ("Proposed Project"). The Proposed Project involves treating secondary effluent from the MRWPCA Regional Treatment Plant (RTP) through the proposed Advanced Water Treatment Facility (AWT Facility) and then injecting this highly purified recycled water into the Seaside Groundwater Basin, later extracting it for replacement of existing municipal water supplies. The Proposed Project will also provide additional tertiary recycled water for agricultural irrigation in northern Salinas Valley as part of the Castroville Seawater Intrusion Project (CISP). A waste stream, known as the reverse osmosis concentrate ("RO concentrate"), would be generated by the AWT Facility and discharged through the existing MRWPCA ocean outfall. The goal of this technical memorandum is to analyze whether the discharge of the Proposed Project's RO concentrate to the ocean through the existing outfall would impact marine water quality, and thus, human health, marine biological resources, or beneficial uses of the receiving waters.

## 1.1 Treatment through the RTP and AWT Facility

The existing MRWPCA RTP treatment process includes screening, primary sedimentation, secondary biological treatment through trickling filters (TFs), followed by a solids contactor (*i.e.*, bio-flocculation), and then clarification (Figure 1). Much of the secondary effluent undergoes tertiary treatment (granular media filtration and disinfection) to produce recycled water used for agricultural irrigation. The unused secondary effluent is discharged to the Monterey Bay through the MRWPCA Outfall. MRWPCA also accepts trucked brine waste for ocean disposal, which is stored in a pond and mixed with secondary effluent for disposal.

The proposed AWT Facility would include several advanced treatment technologies for purifying the secondary effluent water: ozone ($O_3$), biologically active filtration (BAF) (this is an optional unit process), membrane filtration (MF), reverse osmosis (RO), and an advanced oxidation process (AOP) using UV-hydrogen peroxide. The Project Partners conducted a pilot-scale study of the ozone, MF, and RO elements of the AWT Facility from December 2013 through July 2014, successfully demonstrating the ability of the various treatment processes to produce highly-purified recycled water that complies with the California Groundwater Replenishment Using Recycled Water Regulations (Groundwater Replenishment Regulations) and Central Coast Water Quality Control Plan (Basin Plan) standards, objectives and guidelines for groundwater.

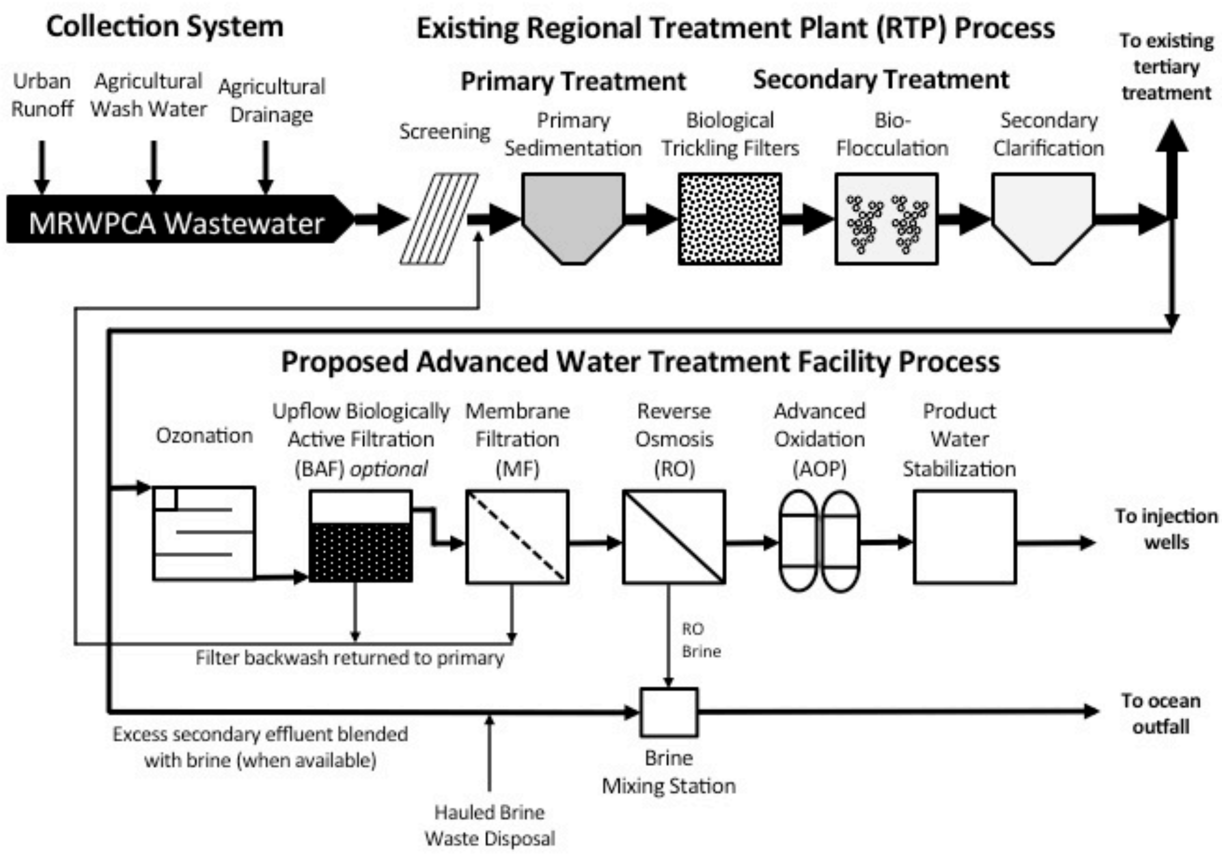

**Figure 1 – Simplified diagram of existing MRWPCA RTP and proposed AWT Facility treatment**

Reverse osmosis is an excellent removal process, separating out most dissolved constituents from the recycled water. The dissolved constituents removed through RO are concentrated into a waste stream known as the RO concentrate. Unlike the waste streams from the BAF and MF, the RO concentrate cannot be recycled back to the RTP headworks and would be discharged through the MRWPCA Outfall. Discharges through the outfall are subject to National Pollution Discharge Elimination System (NPDES) permitting, which is based on the California State Water Resources Control Board 2012 Ocean Plan ("Ocean Plan"). Monitoring of the RO concentrate was conducted during the Proposed Project's pilot-scale study.

## 1.2 California Ocean Plan

The Ocean Plan sets forth water quality objectives for ocean discharges with the intent of preserving the quality of the ocean water for beneficial uses, including the protection of both human and aquatic ecosystem health (SWRCB, 2012). For typical wastewater discharges, when released from an outfall, the wastewater and ocean water undergo rapid mixing due to the momentum and buoyancy of the discharge.[1] The mixing occurring in the rising plume is affected

[1] Municipal wastewater effluent, being effectively fresh water, is less dense than seawater and thus rises (due to buoyancy) while it mixes with ocean water.

by the buoyancy and momentum of the discharge, a process referred to as initial dilution (NRC, 1993). The Ocean Plan objectives are to be met after the initial dilution of the discharge into the ocean. The initial dilution occurs in an area known as the zone of initial dilution (ZID). The extent of dilution in the ZID is quantified as the minimum probable initial dilution ($D_m$). The water quality objectives established in the Ocean Plan are adjusted by the $D_m$ to derive the NPDES ocean discharge limits for a wastewater discharge prior to ocean dilution.

The current MRWPCA wastewater discharge is governed by NPDES permit R3-2014-0013 issued by the Central Coast Regional Water Quality Control Board (RWQCB). Because the existing NPDES permit for the MRWPCA ocean outfall must be amended to discharge the RO concentrate, comparing future discharge concentrations to current NPDES permit limits would not be an appropriate metric or threshold for determining whether the Proposed Project would have a significant impact on marine water quality. Instead, compliance with the Ocean Plan objectives was selected as an appropriate threshold for determining whether or not the Proposed Project would result in a significant impact requiring mitigation. Modeling of the Proposed Project ocean discharge was conducted by FlowScience, Inc. to determine $D_m$ values for the various discharge scenarios. The ocean modeling results were combined with projected discharge water quality to assess compliance with the Ocean Plan.

## 1.3 Objective of Technical Memorandum

Trussell Technologies, Inc. (Trussell Tech) estimated worst-case water quality for the Proposed Project ocean discharge water in-pipe (*i.e.*, prior to being discharged through the outfall and diluted in the ocean) and used the FlowScience ocean discharge modeling results to provide an assessment of whether the Proposed Project would consistently meet Ocean Plan water quality objectives. The purpose of this technical memorandum is to summarize the assumptions, methodology, results and conclusions of the Ocean Plan compliance assessment.

# 2 Methodology for Ocean Plan Compliance

To analyze impacts due to ocean discharge of RO concentrate, the Proposed Project technical team (Trussell Tech with MRWPCA staff) conducted a thorough water quality and flow characterization of the proposed sources of water to be diverted into the wastewater collection system that, after primary and secondary treatment, will be used as influent to the AWT Facility. The team collected all available water quality data for secondary effluent and water quality monitoring results for the Proposed Project new source waters.[2] Using the full suite of data, the team was able to estimate the future worst-case water quality of the combined ocean discharge. With the results of ocean modeling, concentrations at the edge of the ZID were estimated to determine the ability of the Proposed Project to comply with the Ocean Plan. The purpose of this section is to outline the methodology used to make this determination. A summary of the methodology is presented in Figure 2.

## 2.1 Methodology for Determination of Discharge Water Quality

Water quality data for three types of discharge waters were used to estimate the future combined water quality in the ocean outfall discharge under Proposed Project conditions: (1) the RTP secondary effluent, (2) hauled brine waste (discussed in Section 2.1.3), and (3) the Proposed Project RO concentrate. First, Trussell Tech estimated the potential influence of the new source waters (*e.g.*, agricultural wash water and agricultural drainage waters) on the worst-case water quality for each of the three types of discharge water. The volumetric contribution of each new source water would change under the different flow scenarios that could occur under the Proposed Project. MRWPCA staff estimated the volume that would be collected from source water for each month of the different types of operational years for the Proposed Project (Bob Holden, Source Water Scenarios Spreadsheet, October 16, 2014)[3]. All of the different flow scenarios were considered in developing the assumed worst-case concentrations for the Ocean Plan constituents in the secondary effluent. This conservative approach used the highest observed concentrations from all data sources for each source water in the analysis[4]. Once the estimated worst-case water quality was determined for the RTP secondary effluent, these values were used in estimating the worst-case water qualities for the hauled brine waste and the

[2] A one-year monitoring program from July 2013 to June 2014 was conducted for five of the potential source waters. Regular monthly and quarterly sampling was carried out for the RTP secondary effluent, agricultural wash water, and Blanco Drain drainage water. Limited sampling of stormwater from Lake El Estero was performed due to seasonal availability, and there was one sampling event for the Tembladero Slough drainage water.

[3] The monthly flows for each source water were estimated by MRWPCA staff for three types of operational years: (1) wet/normal years where a drought reserve is being built, (2) wet/normal years where the drought reserve has been met, and (3) a drought year. Further, two phases of the Proposed Project have been defined for each of these types of years (Phase A and Phase B).

[4] The exception to this statement is cyanide. Only cyanide data collected from April 2005 through January 2011, as part of the NPDES monitoring program, were used in the analysis. In mid-2011, Monterey Bay Analytical Service (MBAS) began performing the cyanide analysis on the RTP effluent, at which time the reported values increased by an order of magnitude. Because no operational or source water composition changes took place at this time that would result in such an increase, it is reasonable to conclude the increase is an artifact of the change in analysis method and therefore the results were questionable. Therefore, although the cyanide concentrations reported by MBAS are presented separately; they are not used in the analysis for evaluating compliance with the Ocean Plan objectives for the EIR.

Proposed Project RO concentrate, as appropriate. The methodology for each type of water is further described in this section.

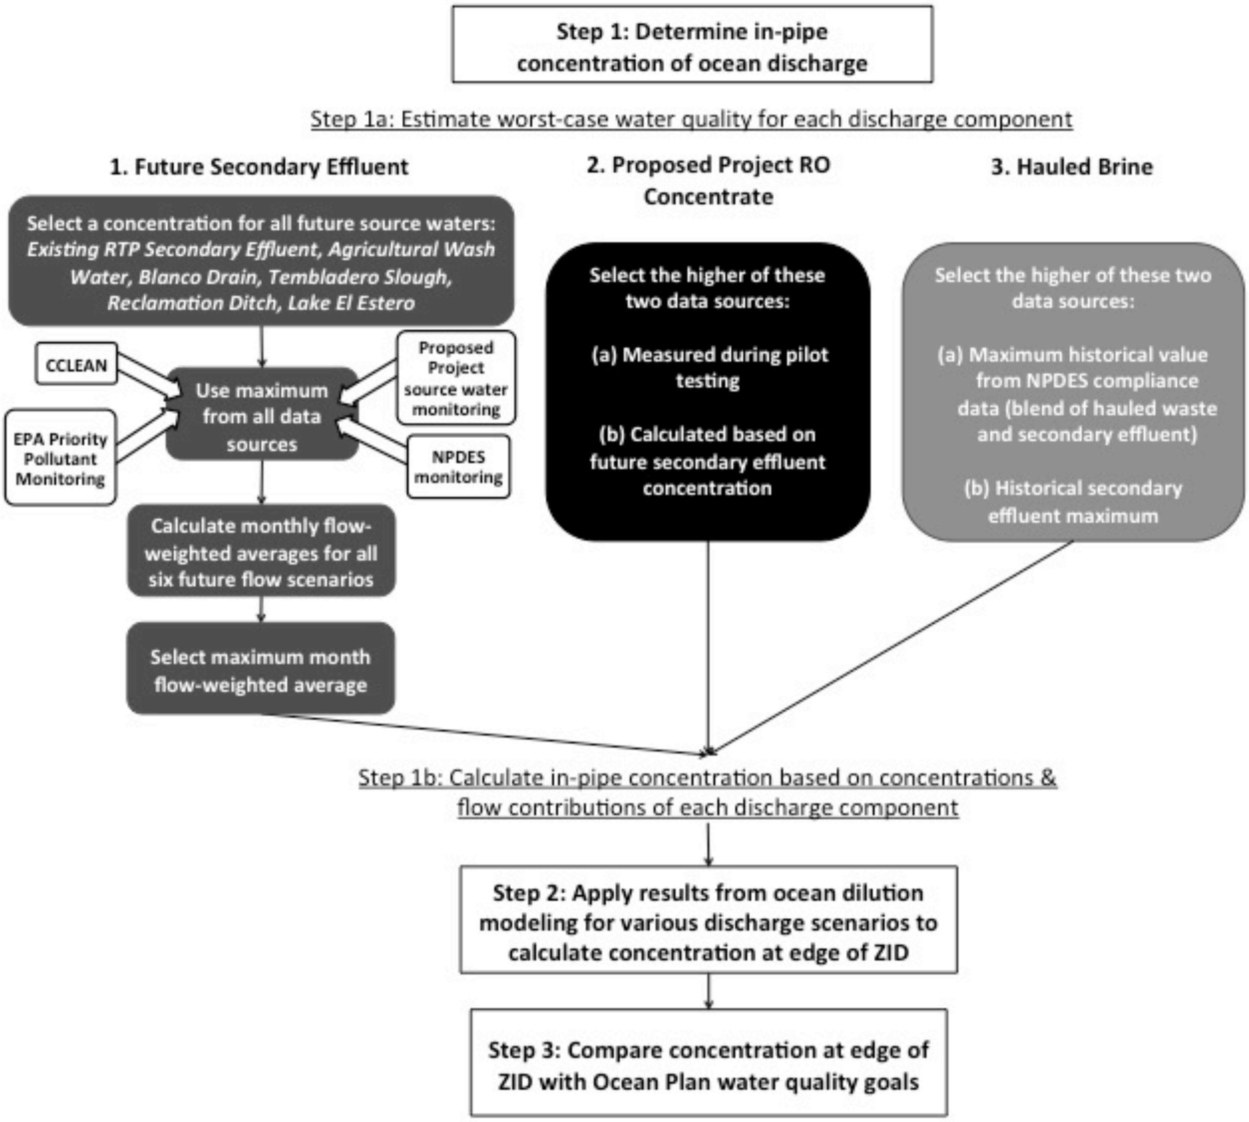

**Figure 2 – Logic flow-chart for determination of project compliance with the Ocean Plan objectives**

### 2.1.1 Future Secondary Effluent

Because the Proposed Project involves bringing new source waters into the RTP, the water quality of those source waters as well as the existing secondary effluent needed to be taken into account to estimate the water quality of the future secondary effluent. The following sources of data were considered for selecting an existing secondary effluent concentration for each constituent in the analysis:

- Source water monitoring conducted for the Proposed Project from July 2013 through June 2014
- Historical NPDES compliance data collected semi-annually by MRWPCA (2005-2014)

- Historical Priority Pollutant data collected annually by MRWPCA (2004-2014)
- Data collected by the Central Coast Long-Term Environmental Assessment Network (CCLEAN) (2008-2013)

The existing secondary effluent concentration for each constituent selected for the analysis was the maximum reported value from the above sources.

Only one data source was available for several of the new source waters (*i.e.*, agricultural wash water, Blanco Drain, Tembladero Slough, and the Reclamation Ditch[5]), namely, data collected during the source water monitoring conducted for the Proposed Project. From these data, the maximum observed concentration was selected for each source water.

Source water flows used for calculation of blended future secondary effluent concentrations were taken from the six projected operational conditions prepared by MRWPCA staff – Phase A and B for the three conditions: (a) normal/wet year, building reserve, (b) normal/wet year, full reserve, and (c) drought year[6]. For each constituent, a total of 72 future concentrations were calculated – 12 months of the year for the 6 projected future source water flow contributions. Of these concentrations, a maximum monthly flow-weighted concentration was selected for each constituent to be used for the Ocean Plan compliance analysis.

When a constituent cannot be quantified or is not detected, it is reported as less than the Method Reporting Limit (<MRL).[7] Because the actual concentration could be any value equal to or less than the MRL, the conservative approach is to use the value of the MRL in the flow-weighting calculations. In some cases, constituents were not detected in any of the source waters; in this case, the values are reported as ND(<X), where X is the MRL. For some non-detected constituents, the MRL exceeds the Ocean Plan objective, and thus no compliance determination can be made[8].

---

[5] For the Reclamation Ditch, water quality data related to the Ocean Plan were not available. Concentrations for the Reclamation Ditch were conservatively assumed to be the higher of either the Blanco Drain or Tembladero Slough concentration.

[6] An alternative scenario exists in which all reasonably available source waters are diverted to the RTP regardless of whether there is demand for recycled water (spreadsheet provided by Larry Hampson, October 17, 2014). This scenario was not evaluated here because it would represent an unlikely flow scenario in which there would be RTP effluent discharged to the ocean in the summer months. Trussell Technologies performed an analysis using this alternative scenario and estimated that the concentrations of the Ocean Plan constituents would be less than or equal to the estimated concentrations of the primary scenarios used in this memorandum, and thus further analysis of the alternative scenario is not included.

[7] The lowest amount of an analyte in a sample that can be quantitatively determined with stated, acceptable precision and accuracy under stated analytical conditions (*i.e.*, the lower limit of quantitation). Therefore, acceptable quality control and quality assurance procedures are calibrated to the MRL, or lower. To take into account day-to-day fluctuations in instrument sensitivity, analyst performance, and other factors, the MRL is established at three times the Method Detection Limit (or greater). The Method Detection Limit is the minimum concentration of a substance that can be measured and reported with 99% confidence that the analyte concentration is greater than zero. (40 Code of Federal Regulations Section136 Appendix B).

[8] This phenomenon is common in the implementation of the Ocean Plan where for some constituents, suitable analytical methods are not capable of measuring low enough to quantify the minimum toxicologically relevant concentrations. For these constituents, a discharge is considered compliant if the monitoring results are less than the MRL.

The following approaches were used for addressing the cases where a constituent was reported as less than the MRL:

- **Aggregate constituents with multiple congeners or sub-components:** Some Ocean Plan constituents are a combination of multiple congeners or sub-components (*e.g.*, chlordane, PAHs, PCBs, and TCDD equivalents). Per the Ocean Plan, if individual congeners or sub-components are below the MRL, they are assumed to be zero for the purposes of calculating the aggregate parameter.
- **Combining different types of waters:** The same approach to constituents that were below the MRL was used for both combining different source waters (*i.e.*, predicting future secondary effluent concentrations based on source water contributions) *and* for combining the different discharge components (*i.e.*, RTP secondary effluent, hauled brine, and RO concentrate). For each constituent:
    - ***When all waters had maximum values reported above the MRL*:** The flow-weighted average of the maximum detected concentrations was used when all water had values reported above the MRL.
    - ***When some waters had maximum values reported as less than the MRL*:**
        - When the MRL was *more* than two orders of magnitude greater (*i.e.*, more than 100 times greater) than the highest detected value from the other waters, the waters with maximum concentrations below the MRL were ignored (*i.e.* treated as having a concentration of zero). This case is exclusive to times when CCLEAN data were reported as detections for the RTP secondary effluent, and all of the other source waters were below the MRL[9]. The analytical methods used for CCLEAN are capable of detecting concentrations many orders of magnitude below the detection limits for traditional methods, and thus to include the <MRL from the other methods would overshadow the CCLEAN data. Additionally, in cases where the traditional analytical method had an MRL greater than the Ocean Plan objective, performing the analysis using the high MRL from the non-CCLEAN methods would result in an inability to make a compliance determination for these constituents.
        - When the MRL was *within* two orders of magnitude or less (*i.e.*, less than 100 times greater) than the highest detected value from the other waters, the constituents that were reported as less than the MRL and were assumed to have a concentration at the MRL for the purposes of calculating a flow-weighted average.
    - ***All waters had maximum values reported as less than the MRL*:** A flow-weighted average MRL was calculated for the constituent and the result was reported as less than this combined MRL. For constituents where multiple MRLs exist for the same water (due to different laboratory analysis methods or dilutions), the lowest MRL was used.

[9] Specifically, this case applies to endrin, chlordane, heptachlor epoxide, hexachlorobenzene, hexachlorobutadiene, PCBs, and toxaphene.

### 2.1.2 GWR RO Concentrate

Two potential worst-case concentrations were available for the Proposed Project RO concentrate:

- Measured in the concentrate during pilot testing
- Calculated from the blended future secondary effluent concentration, using the following treatment assumptions[10]:
  - No removal prior to the RO process (*i.e.*, at the RTP or AWT Facility ozone or MF)
  - 81% RO recovery (*i.e.*, of the water feeding into the RO system, 81% is product water, also known as permeate, and 19% is the RO concentrate)
  - Complete rejection of each constituent by the RO membrane

The higher of these two values was selected as the final concentration of the RO concentrate for all constituents, except as noted in the Appendix footnotes.

### 2.1.3 Hauled Brine

Currently, small volumes of brine water are trucked to the RTP and blended with secondary effluent in a brine pond. The waste from this pond ("hauled brine") is then discharged along with the secondary effluent bound for ocean discharge (if there is any). For the Proposed Project, the hauled brine would be discharged with both secondary effluent and RO concentrate (see Figure 1). The point at which the hauled brine is added to the ocean discharge water is downstream of the AWT Facility intake, and thus it would not impact the quality of the Proposed Project product water or the RO concentrate. Currently, all sampling of the hauled brine takes place after dilution by secondary effluent in the brine pond, and so the data represent a mix of secondary effluent and brine water. It is appropriate to use these data for the hauled brine quality since the practice of diluting with secondary effluent will continue in the future. Two potential values were available for the hauled brine concentration:

- Historical NPDES compliance data collected semi-annually by MRWPCA (2005-2013) of hauled brine water diluted with existing secondary effluent
- Future secondary effluent concentration, as previously described

The higher of these two values was selected for all constituents; because the hauled brine is diluted by secondary effluent prior to discharge, it is also appropriate to use future secondary effluent concentrations to represent the concentration within hauled brine. Even if a constituent were not present in the hauled brine, if it is present in the secondary effluent it would be present in the combined discharge.

### 2.1.4 Combined Ocean Discharge Concentrations

Having calculated the worst-case future concentrations for each of the three discharge components, the combined concentration prior to discharge was determined as a flow-weighted average of the contributions of each of the three discharge components. As discussed in Section 3.1, a range of secondary effluent flow conditions was considered.

[10] Based on the treatment assumptions, the RO concentrate would equal 5.3 times the AWT Facility influent (*i.e.*, blended future secondary effluent) concentration.

## 2.2 Ocean Modeling and Ocean Plan Compliance Analysis Methodology

In order to determine Ocean Plan compliance, Trussell Tech used the following information: (1) the in-pipe (*i.e.*, pre-ocean dilution) concentration of a constituent ($C_{\text{in-pipe}}$) that was developed as discussed in the previous section, (2) the minimum probable dilution for the ocean mixing ($D_m$) for the relevant discharge flow scenarios that was modeled by FlowScience (FlowScience, 2014), and (3) the background concentration of the constituent in the ocean ($C_{Background}$) that is specified in the Ocean Plan's "Table 3". With this information the concentration at the edge of the zone of initial dilution ($C_{ZID}$) was calculated using the following equation:

$$C_{ZID} = \frac{C_{In-pipe} + D_m * C_{Background}}{1 + D_m} \qquad (1)$$

The $C_{ZID}$ was then compared to the Ocean Plan objectives[11] in the Ocean Plan's "Table 1" (SWRCB, 2012). As described previously, the in-pipe concentration was estimated as a flow-weighted average of the future secondary effluent, Proposed Project RO concentrate, and hauled brine with the concentrations determined as discussed above. The $D_m$ values for various flow scenarios were determined by modeling (see FlowScience, 2014). Note that this approach could not be applied for some constituents (*e.g.*, acute toxicity, chronic toxicity, and radioactivity[12]). The assumptions used by FlowScience for the ocean discharge dilution modeling are as follows:

- **Flow**: A sensitivity analysis of relationship between $D_m$ and flow rate was performed for the various discharges types. The greatest $D_m$ sensitivity to flow changes was to variations in the RTP secondary effluent flow. To simplify the analysis, the flow scenarios used in the compliance analysis only considered the maximum flows for the hauled brine and the RO concentrate, because these flows result in the lowest $D_m$, thus making the analysis conservative. The flows considered for each discharge type are as follows:
  - ***Secondary effluent*****:** a range of conditions was modeled that reflect realistic future discharge scenarios (minimum flow, moderate flow, and maximum flow).
  - ***Proposed Project RO concentrate*****:** 0.94 million gallons per day (mgd), which would be the resulting RO concentrate flow when the AWT Facility is producing

[11] Note that the Ocean Plan (see Ocean Plan Table 2) also defines effluent limitations for oil and grease, suspended solids, settable solids, turbidity, and pH; however, it was not necessary to evaluate these parameters in this assessment. If necessary, the pH of the water would be adjusted to be within acceptable limits prior to discharge. Oil and grease, suspended solids, settable solids, and turbidity do not need to be considered in this analysis as the RO concentrate would be significantly better than the secondary effluent with regards to these parameters. Prior to the RO treatment, the process flow would be treated by MF, which will reduce these parameters, and the waste stream from the MF will be returned to RTP headworks.

[12] Calculating flow-weighted averages for toxicity (acute and chronic) and radioactivity (gross beta and gross alpha) is not appropriate based on the nature of the constituent. These constituents were measured individually for the secondary effluent and RO concentrate, and these individual concentrations would comply with the Ocean Plan objectives (Trussell Technologies, 2014 and 2015). See section 3.4.

4.0 mgd of highly-purified recycled water (corresponds to treating 5.49 mgd of RTP secondary effluent); although the AWT Facility will not be operated at this influent flowrate year round, this is the highest potential RO concentrate flow
    - ***Hauled brine:*** 0.1 mgd, which is the maximum anticipated value (blend of secondary effluent and hauled brine) anticipated by MRWPCA.
- **Total Dissolved Solids (TDS)**: the greatest dilution is achieved when the salinity of the discharge water is the most different from the ambient salinity; therefore, the most conservative TDS will be the highest (*i.e.*, closest to ambient salinity) of:
    - ***Secondary effluent:*** 1,100 milligram per liter (mg/L), which is the maximum expected future TDS, taking into account the flow contribution of each source water and the maximum observed TDS value from each source water
    - ***Proposed Project RO concentrate*****:** 5,800 mg/L, which is the maximum expected future TDS based on the maximum expected future secondary effluent TDS and the RO treatment assumptions listed in the section above (*i.e.* in a drought year).
    - ***Hauled brine***: 40,000 mg/L, which is the maximum anticipated value (blend of secondary effluent and hauled brine) from MRWPCA.
- **Ambient salinity**: 33,500 mg/L
- **Temperature**: 20°C

An additional consideration of the ocean dilution modeling is the variation in ocean conditions throughout the year. Three conditions were modeled for all flow scenarios: Davidson (November to March), Upwelling (April to August), and Oceanic (September to October)[13]. In order to conservatively demonstrate Ocean Plan compliance, the lowest $D_m$ from the applicable ocean conditions was used for each flow scenario.

Ocean dilution modeling covered a range of secondary effluent flowrates between 0 and 24.7 mgd[14], and the results showed that Ocean Plan compliance would be achieved when considering all potential secondary effluent flowrates. To simplify the calculation and presentation of these results, representative flowrate ranges were chosen. In order to select the representative flow scenarios to use for the compliance assessment, the balance between in-pipe dilution and dilution through the outfall needed to be taken into account. In general, higher secondary effluent flows being discharged to the ocean would provide dilution of the Proposed Project RO concentrate; however, greater dilution due to ocean water mixing would be provided at lower wastewater discharge flows. The balance of these influences was considered in determining compliance under the five representative discharge conditions that are described in Section 3.2 for the Proposed Project.

---

[13] Note that these ranges assign the transitional months to the ocean condition that is typically more restrictive at relevant discharge flows.

[14] The 24.7 mgd represents the secondary effluent flow if the RTP is operating at its design capacity of 29.6 mgd, and there is a net flow of 4.9 mgd to the AWT Facility (a total flow of approximately 5.46 mgd would be sent to the AWT Facility, but 0.55 mgd of MF backwash water is returned to the RTP headworks from the AWT Facility).

# 3 Ocean Plan Compliance Results

## 3.1 Water Quality of Combined Discharge

As described above, the first step in the Ocean Plan compliance analysis was to estimate the worst-case water quality for each of the three future discharge components: future RTP effluent, Proposed Project RO concentrate, and hauled brine waste. A summary of the estimated water qualities of these components is given in Table 1. Additional considerations and assumptions for each constituent are documented in the Table 1 notes section.

**Table 1 – Summary of estimated worst-case water quality for the three waters that would be discharged through the ocean outfall**

| Constituent | Units | Secondary Effluent | Hauled Brine | RO Concentrate | Notes |
|---|---|---|---|---|---|
| ***Ocean Plan water quality objectives for protection of marine aquatic life*** | | | | | |
| Arsenic | µg/L | 45 | 45 | 12 | 1,12 |
| Cadmium | µg/L | 1.2 | 1.2 | 6.4 | 2,11 |

## Table 1 Notes:

***RTP Effluent and Hauled Brine Data***

[1] Existing RTP effluent exceeds concentrations observed in other proposed source waters; the value reported is the existing secondary effluent value.
[2] The proposed new source waters may increase the secondary effluent concentration; the value reported is based on predicted source water blends.
[3] RTP effluent value is based on CCLEAN data; no other source waters were considered due to MRL differences.
[4] MRL provided represents the maximum flow-weighted MRL based on the blend of source waters.
[5] The only water with a detected concentration was the RTP effluent, however the flow-weighted concentration increases due to higher MRLs for the proposed new source waters.
[6] Additional source water data are not available; the reported value is for RTP effluent.
[7] Calculation of the flow-weighted concentration was not feasible due to constituent and the maximum observed value reported.
[8] Agricultural Wash Water data are based on an aerated sample, instead of a raw water sample.
[9] This value in the Ocean Plan is an aggregate of several congeners or compounds. Per the approach described in the Ocean Plan, for cases where the individual congeners/compounds were less than the MRL, a value of 0 is assumed in calculating the aggregate value, as the MRLs span different orders of magnitude.
[10] For all waters, it is assumed that dechlorination will be provided when needed such that the total chlorine residual will be below detection.

***RO Concentrate Data***

[11] The value presented represents a calculated value assuming no removal prior to RO, complete rejection through RO membrane, and an 81% RO recovery.
[12] The value represents the maximum value observed during the pilot testing study.
[13] The calculated value for the RO concentrate data (described in note 11) was not used in the analysis because it was not considered representative. It is expected that the value would increase as a result of treatment through the AWT Facility (*e.g.* formation of N-Nitrosodimethylamine as a disinfection by-product), or that it will not concentrate linearly through the RO (*e.g.* toxicity and radioactivity).
[14] The MRL provided represents the limit from the source water and pilot testing monitoring programs.
[15] The value presented represents a calculated value assuming 20% removal through primary and secondary treatment, 70% and 90% removal through ozone for DDT and dieldrin, respectively (based on Oram, 2008), complete rejection through the RO membrane, and an 81% RO recovery. The assumed RTP concentrations for Dieldrin and DDT do not include contributions from the agricultural drainage waters. This is because in all but one flow scenario (Scenario 4, described later), either the agricultural drainage waters are not being brought into the RTP because there is sufficient water from other sources (*e.g.* during wet and normal precipitation years), or the RTP effluent is not being discharged to the outfall (*e.g.*, summer months). In this one scenario (Scenario 4), there is a minimal discharge of secondary effluent to the ocean during a drought year under Davidson ocean conditions; for this flow scenario only, different concentrations are assumed for the RTP effluent. DDT and dieldrin concentrations of 0.022 μg/L and 0.0056 μg/L were used for Scenario 4 in the analysis.

***Cyanide Data***

[16] In mid-2011, MBAS began performing the cyanide analysis on the RTP effluent, at which time the reported values increased by an order of magnitude. Because no operational or source water composition changes took place at this time that would result in such an increase, it is reasonable to conclude the increase is an artifact of the change in analysis method and therefore questionable. Therefore, the cyanide values as measured by MBAS are listed separately from other cyanide values, and the MBAS data were not be used in the analysis for evaluating compliance with the Ocean Plan objectives for the EIR.

## 3.2 Ocean Modeling Results

FlowScience performed modeling of various discharges that include combinations of RTP secondary effluent, hauled brine waste, and Proposed Project RO concentrate (FlowScience, 2014). Year-round compliance with the Ocean Plan objectives was assessed through the evaluation of five representative discharge scenarios. All scenarios assume the maximum flow rates for the RO concentrate and hauled brine waste, which is a conservative assumption in terms of constituent loading and minimum dilution. Various secondary effluent flows were used in the compliance analysis, which represent the different types of future discharge compositions.

The five scenarios used for the compliance assessment in terms of secondary effluent flows to be discharged with the other discharges are shown in Table 2, and include:

(1) **RTP Design Capacity:** maximum flows for the Proposed Project with all 172 discharge ports open[15]. The Oceanic ocean condition was used as it represents the worst-case dilution for this flow scenario. This scenario represents the maximum (NPDES) permitted wastewater flow (with the Proposed Project in operation).

(2) **Maximum Flow under Current Port Configuration:** the maximum flow that can be discharged with the current ports configuration (130 of the 172 ports open)[16]. The Oceanic ocean condition was used as it represents the worst-case dilution for this flow scenario. This scenario was chosen as it represents the maximum wastewater flow under the existing diffuser conditions.

(3) **Minimum Wastewater Flow (Oceanic/Upwelling):** the maximum influence of the Proposed Project RO concentrate on the ocean discharge under Oceanic/Upwelling ocean conditions (*i.e.*, no secondary effluent discharged). The Oceanic ocean condition was used as it represents the worst-case dilution for this flow scenario.

(4) **Minimum Wastewater Flow (Davidson):** the maximum influence of the Proposed Project RO concentrate on the ocean discharge under Davidson ocean condition (*i.e.*, the minimum wastewater flow). Observed historic wastewater flows generally exceed 0.4 mgd during Davidson oceanic conditions. Additional source waters would be brought into the RTP if necessary to maintain the 0.4 mgd minimum.

(5) **Moderate Wastewater Flow:** conditions with a moderate wastewater flow when the Proposed Project RO concentrate has a greater influence to the water quality than in Scenarios 1 and 2, but where the ocean dilution ($D_m$) is reduced due to the higher overall discharge flow (*i.e.*, compared to Scenarios 2 and 3). The Davidson ocean condition was used as it represents the worst-case dilution for this flow scenario.

---

[15] Note that this scenario would only apply if wastewater flows increased to the point that MRWPCA took action to open the 42 discharge ports that are currently closed. Scenario 2 is the maximum discharge flow under the current port configuration.

[16] For Scenarios 2 through 5, ocean modeling was performed assuming 120 ports open, which would yield more conservative $D_m$ values than 130 ports, as dilution increases with increasing numbers of open ports.

**Table 2 – Flow scenarios and modeled $D_m$ values used for Ocean Plan compliance analysis**

| No. | Discharge Scenario (Ocean Condition) | Flows (mgd) | | | $D_m$ |
|---|---|---|---|---|---|
| | | Secondary effluent | RO concentrate | Hauled brine | |
| 1 | RTP Design Capacity (Oceanic) | 24.7 | 0.94 | 0.1 | 150 |
| 2 | RTP Capacity with Current Port Configuration (Oceanic) | 23.7 | 0.94 | 0.1 | 137 |
| 3 | Minimum Wastewater Flow (Oceanic) | 0 | 0.94 | 0.1 | 523 |
| 4 | Minimum Wastewater Flow (Davidson) | 0.4 | 0.94 | 0.1 | 285 |
| 5 | Moderate Wastewater Flow Condition (Davidson) | 3 | 0.94 | 0.1 | 201 |

## 3.3 Ocean Plan Compliance Results

The flow-weighted in-pipe concentration for each constituent was then calculated for each discharge scenario using the water quality presented in Table 1 and the flows presented in Table 2. The in-pipe concentration was then used to calculate the concentration at the edge of the ZID using the $D_m$ values presented in Table 2. The resulting concentrations for each constituent in each scenario were compared to the Ocean Plan objective to assess compliance. The estimated concentrations for all five flow-scenarios are presented as concentrations at the edge of the ZID (Table 3) and as a percentage of the Ocean Plan objective (Table 4). As shown, none of the constituents are expected to exceed 80% of their Ocean Plan objective[17].

**Table 3 – Predicted concentrations of Ocean Plan constituents at the edge of the ZID**

| Constituent | Units | Ocean Plan Objective | Estimated Concentrations at Edge of ZID by Discharge Scenario | | | | |
|---|---|---|---|---|---|---|---|
| | | | 1 | 2 | 3 | 4 | 5 |
| ***Objectives for protection of marine aquatic life*** | | | | | | | |
| Arsenic | ug/L | 8 | 3.3 | 3.3 | 3.0 | 3.1 | 3.2 |
| Cadmium | ug/L | 1 | 0.009 | 0.01 | 0.01 | 0.02 | 0.01 |
| Chromium (Hexavalent) | ug/L | 2 | 0.02 | 0.03 | 0.05 | 0.07 | 0.04 |
| Copper | ug/L | 3 | 2.2 | 2.2 | 2.2 | 2.3 | 2.2 |

| Silver | ug/L | 0.7 | <0.17 | <0.17 | <0.16 | <0.16 | <0.17 |
| Zinc | ug/L | 20 | 8.3 | 8.3 | 8.4 | 8.6 | 8.4 |
| Cyanide (MBAS data) | ug/L | 1 | 0.61 | 0.66 | 0.26 | 0.44 | 0.50 |
| Cyanide | ug/L | 1 | 0.056 | 0.062 | 0.074 | 0.105 | 0.076 |
| Total Chlorine Residual | ug/L | 2 | <1.3 | <1.4 | <0.4 | <0.7 | <1.0 |
| Ammonia (as N) - 6-mo median | ug/L | 600 | 279 | 306 | 337 | 481 | 359 |
| Ammonia (as N) - Daily Max | ug/L | 2,400 | 375 | 413 | 454 | 648 | 483 |

[17] Aldrin, benzidine, 3,3-dichlorobenzidine and heptachlor were not detected in any source waters, however their MRLs are greater than the Ocean Plan objective. Therefore, no percentages are presented Table 4 as no compliance conclusions can be drawn for these constituents. This is a typical occurrence for ocean discharges since the MRL is higher than the ocean plan objective for some constituents.

| Constituent | Units | Ocean Plan Objective | Estimated Concentrations at Edge of ZID by Discharge Scenario | | | | |

[a] Calculating flow-weighted averages for toxicity (acute and chronic) and radioactivity (gross beta and gross alpha) is not appropriate based the nature of the constituent. These constituents were measured individually for the secondary effluent and RO concentrate, and these individual concentrations would comply with the Ocean Plan objectives (see Section 3.4).
[b] All observed values from all data sources were below the MRL, and the flow-weighted average of the MRLs is higher than the Ocean Plan objective. No compliance conclusions can be drawn for these constituents.
[c] Note that if the percentage as determined by using the MRL was less than 0.01 percent, then a minimum value is shown as "<0.01%" (*e.g.*, if the MRL indicated the value was <0.000001%, for simplicity, it is displayed as <0.01%).

## 3.4 Toxicity

The NPDES permit includes daily maximum effluent limitations for acute and chronic toxicity that are based on the current allowable $D_m$ of 145. The acute toxicity effluent limitation is 4.7 TUa (acute toxicity units) and the chronic toxicity effluent limitation is 150 TUc (chronic toxicity units). The permit requires that toxicity testing be conducted twice per year, with one sample collected during the wet season when the discharge is primarily secondary effluent and once during the dry season when the discharge is primarily trucked brine waste. The MRWPCA ocean discharge has consistently complied with these toxicity limits (CCRWQCB, 2014).

Toxicity testing of RO concentrate generated by the pilot testing was conducted in support of the Proposed Project (Trussell Technologies, 2015). On April 9, 2014, a sample of RO concentrate was sent to Pacific EcoRisk for acute and chronic toxicity analysis. Based on these results (RO concentrate values presented in Table 1), the Proposed Project concentrate requires a minimum $D_m$ of 16:1 and 99:1 for acute and chronic toxicity, respectively, to meet the Ocean Plan objectives. These $D_m$ values were compared to predicted $D_m$ values for the discharge of concentrate only from the Proposed Project's full-scale AWT Facility and the discharge of concentrate combined with secondary effluent from the RTP. The minimum dilution modeled for the various Proposed Project discharge scenarios was 137:1, which is when the secondary effluent discharge is at the maximum possible flow under the current port configuration (FlowScience, 2014). Given that the lowest expected $D_m$ value for the various Proposed Project ocean discharge scenarios is greater than the required dilution factor for compliance with the Ocean Plan toxicity objectives, this sample illustrates that the discharge scenarios would comply with Ocean Plan objectives.

# 4 Conclusions

The purpose of the analysis documented in this technical memorandum was to assess the ability of the Proposed Project to comply with the Ocean Plan objectives. Trussell Tech used a conservative approach to estimate the water qualities of the RTP secondary effluent, RO concentrate, and hauled brine waste for the Proposed Project. These water quality data were then combined for various discharge scenarios, and a concentration at the edge of the ZID was calculated for each constituent and scenario. Compliance assessments could not be made for selected constituents, as noted, due to analytical limitations, but this is a typical occurrence for these Ocean Plan constituents. Based on the data, assumptions, modeling, and analytical methodology presented in this technical memorandum, the Proposed Project would comply with the Ocean Plan objectives.

# 1 Introduction

Trussell Technologies, Inc. (Trussell Tech) previously prepared two Technical Memoranda to assess compliance of the following three proposed projects with the California Ocean Plan (SWRCB, 2012):

1. **Monterey Peninsula Water Supply Project ("MPWSP")**, which would include a seawater desalination plant capable of producing 9.6 million gallons per day (mgd) of drinking water (Ocean Plan compliance assessment described in Trussell Tech, 2015b).
2. **Pure Water Monterey Groundwater Replenishment Project ("GWR Project"),** which would include an Advanced Water Treatment facility ("AWT Facility") capable of producing an average flow of 3.3 mgd of highly purified recycled water for injection into the Seaside Groundwater Basin (Ocean Plan compliance assessment described in Trussell Tech, 2015a). The AWT Facility source water would be secondary treated wastewater ("secondary effluent") from the Monterey Regional Water Pollution Control Agency's (MRWPCA's) Regional Treatment Plant (RTP).
3. **Monterey Peninsula Water Supply Project Variant or "Variant Project"**, which would be a combination of a smaller seawater desalination plant capable of producing 6.4 mgd of drinking water along with the GWR Project (Ocean Plan compliance assessment described in Trussell Tech, 2015b).

Both the proposed desalination facility and the proposed AWT Facility would employ reverse osmosis (RO) membranes to purify the waters, and as a result, both projects would produce RO concentrate waste streams that would be disposed through the existing MRWPCA ocean outfall: the RO concentrate from the desalination facility ("Desal Brine"), and the RO concentrate from the AWT Facility ("GWR Concentrate"). Additional details regarding the project backgrounds, assessment methodologies, results, and conclusions for discharge of these waste streams are described in the previous Technical Memoranda (Trussell Tech, 2015a and 2015b).

The Ocean Plan objectives are to be met after initial dilution of the discharge in the ocean. The initial dilution occurs in an area known as the zone of initial dilution (ZID). The extent of dilution in the ZID is quantified and referred to as the minimum probable initial dilution ($D_m$). The water quality objectives established in the Ocean Plan are adjusted by the $D_m$ to derive the National Pollutant Discharge Elimination System (NPDES) permit limits for a treated wastewater discharge prior to ocean dilution.

Part of the methodology for estimating the concentration of a constituent for the Ocean Plan is estimating the $D_m$ based on ocean modeling. FlowScience, Inc. ("FlowScience") conducted modeling of mixing in the ocean for various discharge scenarios related to the proposed projects to determine $D_m$ values for the key discharge scenarios. Recently, additional modeling by FlowScience (FlowScience, 2015) was performed to (1) update the number of currently open discharge ports in the MRWPCA ocean outfall from 120 to 130 open ports, (2) update the GWR RO concentrate flow from 0.73 to 0.94 mgd and account for the hauled brine[1] for the MPWSP

[1] The hauled brine is waste that is trucked to the RTP and blended with secondary effluent prior to being discharged. The maximum anticipated flow of this stream is 0.1 mgd (blend of brine and secondary effluent).

and Variant Project discharge scenarios, and (3) model additional key discharge scenarios that were missing from the initial ocean modeling for the MPWSP and Variant Project.

The purpose of this Addendum Report is to provide an understanding of the impact of the updated ocean discharge modeling on the previous Ocean Plan compliance assessments for the various proposed projects.

# 2 Modeling Update Results

FlowScience performed additional ocean discharge modeling for key discharge scenarios (see Appendix A) and Trussell Tech used these modeling results to perform an updated analysis of Ocean Plan compliance for the various proposed projects. Results from these analyses are presented in the following subsections: the MPWSP in Section 2.1; the Variant Project in Section 2.2; and the GWR Project in Section 2.3. Note that the results for the GWR Project in Section 2.3 are also applicable to the Variant Project. Not all previously modeled scenarios were repeated; the scenarios selected for updating were chosen to demonstrate the impact of the updated model input parameters (*i.e.*, number of open ports, inclusion of the hauled waste flow, and GWR Concentrate flow update). In addition, some new scenarios were added to ensure that the worst-case discharge conditions were considered for all of the proposed projects.

## 2.1 Updated Results for the MPWSP

The following discharge scenarios related to the MPWSP were modeled using 130 open ports for the MRWPCA ocean outfall:

1. **Desal Brine with no secondary effluent (*updated scenario*):** The maximum influence of the Desal Brine on the overall discharge (*i.e.*, no secondary effluent discharged) would be when there is no secondary effluent discharged. This scenario would be representative of conditions when demand for recycled water is highest (*e.g.*, during summer months), and all of the RTP secondary effluent is recycled through the Salinas Valley Reclamation Project (SVRP) for agricultural irrigation. The hauled waste is also included in this discharge scenario.
2. **Desal Brine with moderate secondary effluent flow (*new scenario*):** Desal Brine discharged with a relatively moderate secondary effluent flow that results in a plume with slightly negative buoyancy. This scenario represents times when demand for recycled water is low or the secondary effluent flow is low, and there is excess secondary effluent that is discharged to the ocean.

The updated $D_m$ values for these two discharge scenarios are provided in Table 1. The net impact of using 130 open ports and including the hauled waste was a slight increase (approximately 6%) in the amount of dilution associated with ocean mixing. This confirms that previously modeled MPWSP discharge scenarios with Desal Brine included in Trussell 2015b were conservative (*i.e.* the previous analysis slightly over-estimated the ZID concentration for the Ocean Plan constituents).

**Table 1 – Updated minimum probable dilution ($D_m$) values for select MPWSP discharge scenarios**

| No. | Discharge Scenario (Ocean Condition) | Discharge flows (mgd) | | | Previously Reported $D_m$ (120 ports)[a] | Updated $D_m$ (130 ports) |
|---|---|---|---|---|---|---|
| | | Secondary effluent | Hauled Waste | Desal Brine | | |
| 1 | Desal Brine with no secondary effluent flow (Davidson) | 0 | 0.1 | 13.98 | 16 | 17 |
| 2 | Desal Brine with moderate secondary effluent flow (Davidson) | 9 | 0.1 | 13.98 | n/a [b] | 22 |

[a] The previously reported $D_m$ was used in the analysis presented in Trussell 2015b, and was determined with the assumption that 120 ports on the outfall were open and did not consider the hauled waste flow.
[b] Not applicable, as Discharge Scenario 2, consisting of Desal Brine and a moderate secondary effluent flow, was not previously modeled.

The $D_m$ values reported in Table 1 were used to assess the Ocean Plan compliance for MPWSP Scenarios 1 and 2 using the same methodology and water quality assumptions previously described (Trussell, 2015b). The estimated concentrations at the edge of the ZID for constituents that are expected to exceed the Ocean Plan objective are provided in Table 2. A new exceedance was identified in MPWSP Scenario 2, where the ammonia concentration at the edge of the ZID was predicted to exceed the 6-month median Ocean Plan objective. A list of estimated concentrations for these two scenarios for all Ocean Plan constituents is provided in Appendix B (Table A1).

**Table 2 - Predicted concentration at the edge of the ZID expressed for constituents of interest in the MPWSP as both a concentration and percentage of Ocean Plan Objective [a]**

| Constituent | Units | Ocean Plan Objective | MPWSP Ocean Discharge Scenario | | | |
|---|---|---|---|---|---|---|
| | | | Estimated Concentration at Edge of ZID | | Estimated Percentage of Ocean Plan objective at Edge of ZID | |
| | | | 1 | 2 | 1 | 2 |
| Ammonia (as N) – 6-mo median | ug/L | 600 | 19 | 626 | 3% | 104% |
| PCBs | ug/L | 1.9E-05 | 1.2E-04 | 6.7E-05 | 609% | 351% |

[a] Red shading indicates constituent is expected to exceed the ocean plan objective for that discharge scenario.

## 2.2 Updated Results for the Variant Project

The following discharge scenarios related to the Variant Project were modeled using 130 open ports for the MRWPCA ocean outfall:

1. **Desal Brine without secondary effluent or GWR Concentrate (*updated scenario*):** Desal Brine discharged without secondary effluent or GWR Concentrate. This scenario would be representative of conditions when the smaller (6.4 mgd) desalination facility is in operation, but the AWT Facility is not operating (*e.g.*, offline for maintenance), and all of the secondary effluent is recycled through the SVRP (*e.g.*, during high irrigation water demand summer months). The hauled waste is also included in this discharge scenario.
2. **Desal Brine with moderate secondary effluent flow and no GWR concentrate (*new scenario*):** Desal Brine discharged with a relatively moderate secondary effluent flow, but no GWR Concentrate, which results in a plume with slightly negative buoyancy. This

scenario represents times when demand for recycled water is low or the secondary effluent flow is low, and there is excess secondary effluent that is discharged to the ocean. The hauled waste is also included in this discharge scenario.

3. **Desal Brine with GWR Concentrate and no secondary effluent (*updated scenario*):** Desal Brine discharged with GWR Concentrate and no secondary effluent. This scenario would be representative of the condition where both the desalination facility and the AWT Facility are in operation, and there is the highest demand for recycled water through the SVRP (*e.g.*, during summer months). The hauled waste is also included in this discharge scenario.
4. **Desal Brine with GWR Concentrate and a moderate secondary effluent flow (*new scenario*):** Desal Brine discharged with GWR Concentrate and a relatively moderate secondary effluent flow that results in a plume with slightly negative buoyancy. This scenario represents times when both the desalination facility and the AWT Facility are operating, but demand for recycled water is low and there is excess secondary effluent discharged to the ocean. The hauled waste is also included in this discharge scenario.

- **Variant conditions with no Desal Brine contribution**: All scenarios described for the GWR Project are also applicable to the Variant Project. See Section 2.3 for these additional scenarios.

The updated $D_m$ values for these two discharge scenarios are provided in Table 3. Similar to the MPWSP modeling, the net impact of using 130 open ports, including the hauled waste, and using a GWR concentrate flow of 0.94 mgd (instead of 0.73 mgd) was a slight increase (approximately 6%) in the amount of dilution associated with the ocean mixing for the Variant Project discharge scenarios. This confirms that previously modeled Variant discharge scenarios with Desal Brine included in Trussell 2015b were conservative (*i.e.* the previous analysis slightly over-estimated the ZID concentration for the Ocean Plan constituents).

**Table 3 – Updated minimum probable dilution ($D_m$) values for select MPWSP discharge scenarios**

| No. | Discharge Scenario (Ocean Condition) | Discharge flows (mgd) | | | | Previously Reported $D_m$ (120 ports)[a] | Updated $D_m$ (130 ports) |
|---|---|---|---|---|---|---|---|
| | | Secondary effluent | Hauled Waste | GWR Concentrate | Desal Brine | | |
| 1 | Desal Brine with no secondary effluent and no GWR Conc. (Upwelling) | 0 | 0.1 | 0 | 8.99 | 15 | 16 |
| 2 | Desal Brine with moderate secondary effluent flow and no GWR Conc. (Davidson) | 5.8 | 0.1 | 0 | 8.99 | n/a [b] | 22 |
| 3 | Desal Brine and GWR Conc. with no secondary effluent flow (Upwelling) | 0 | 0.1 | 0.94 | 8.99 | 17 | 18 |
| 4 | Desal Brine and GWR Conc. with moderate secondary effluent flow (Upwelling) | 5.3 | 0.1 | 0.94 | 8.99 | n/a [b] | 24 |

[a] The previously reported $D_m$ was used in the analysis presented in Trussell 2015b, and was performed with 120 open ports on the outfall, did not consider the hauled waste flow, and assumed a GWR Concentrate flow of 0.73 instead of 0.94 mgd.

[b] Not applicable, as Discharge Scenarios 2 and 4, with moderate secondary effluent flows, were not previously modeled.

The $D_m$ values reported in Table 3 were used to assess the Ocean Plan compliance for Variant Project Scenarios 1 through 4 using the same methodology and water quality assumptions previously described (Trussell, 2015b). The estimated concentrations at the edge of the ZID for constituents that are expected to exceed the Ocean Plan objective are provided in Table 4. For the updated scenarios (Variant Project Scenarios 1 and 3), the changes to the underlying modeling parameters increased the amount of dilution in the ocean mixing, thus the resulting ZID concentrations decreased slightly. For the new scenarios (Variant Project Scenarios 2 and 4), ammonia was identified as an exceedance in Variant Scenario 2 when there is no GWR Concentrate in the combined discharge. This had not been shown in the previous analysis. A list of estimated concentrations for these four scenarios for all Ocean Plan constituents is provided in Appendix B (Table A2).

**Table 4 - Predicted concentration at the edge of the ZID expressed for constituents of interest in the MPWSP as both a concentration and percentage of Ocean Plan Objective [a]**

| Constituent | Units | Ocean Plan Objective | Variant Project Ocean Discharge Scenario | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|
| | | | Estimated Concentration at Edge of ZID | | | | Estimated Percentage of Ocean Plan objective at Edge of ZID | | | |
| | | | 1 | 2 | 3 | 4 | 1 | 2 | 3 | 4 |
| ***Objectives for protection of marine aquatic life*** | | | | | | | | | | |
| Copper | ug/L | 3 | 2.1 | 2.4 | 2.7 | 2.7 | 70% | 81% | 91% | 90% |
| Ammonia (as N) – 6-mo median | ug/L | 600 | 29 | 629 | 968 | 985 | 4.8% | 105% | 161% | 164% |
| ***Objectives for protection of human health - carcinogens*** | | | | | | | | | | |
| Chlordane | ug/L | 2.3E-05 | 1.2E-05 | 1.8E-05 | 2.9E-05 | 2.4E-05 | 52% | 77% | 125% | 106% |
| DDT | ug/L | 1.7E-04 | 4.6E-05 | 3.9E-05 | 2.1E-04 | 1.2E-04 | 27% | 23% | 122% | 70% |
| PCBs | ug/L | 1.9E-05 | 1.2E-04 | 6.7E-05 | 1.2E-04 | 6.7E-05 | 643% | 351% | 614% | 355% |
| TCDD Equivalents | ug/L | 3.9E-09 | 1.0E-10 | 2.7E-09 | 4.1E-09 | 4.2E-09 | 2.6% | 68% | 104% | 107% |
| Toxaphene | ug/L | 2.1E-04 | 8.0E-05 | 1.6E-04 | 2.5E-04 | 2.2E-04 | 38% | 74% | 119% | 106% |

[a] Shading indicates constituent is expected to be greater than 80 percent (orange shading) or exceed (red shading) the Ocean Plan objective for that discharge scenario.

## 2.3 Updated Results for the GWR Project

The proposed Variant Project is inclusive of the proposed GWR Project, such that the analysis in this section is also part of the Variant Project. The following discharge scenarios related to the GWR Project were modeled using 130 open ports for the MRWPCA ocean outfall:

1. **Maximum Flow under Current Port Configuration (*updated scenario*):** the maximum flow that can be discharged with the current port configuration (130 of the 172 ports open). The Oceanic ocean condition was used as it represents the worst-case dilution for this flow scenario. This scenario was chosen because it represents the maximum secondary effluent flow under existing diffuser conditions.
2. **Minimum Secondary effluent Flow - Oceanic/Upwelling (*updated scenario*):** the maximum influence of the GWR Concentrate on the ocean discharge under Oceanic and Upwelling ocean conditions (*i.e.*, no secondary effluent discharged). The Oceanic ocean condition was used as it represents less dilution for this flow scenario compared to the Upwelling condition.

3. **Minimum Secondary effluent Flow – Davidson (*updated scenario*):** the maximum influence of the GWR Concentrate on the ocean discharge under Davidson ocean condition (*i.e.*, the minimum secondary effluent flow). Observed historic secondary effluent flows generally exceed 0.4 mgd during Davidson oceanic conditions. Additional source waters would be brought into the RTP if necessary to maintain the 0.4 mgd minimum.
4. **Low Secondary effluent Flow (*updated scenario*):** conditions with a relatively low secondary effluent flow of 3 mgd when the GWR Concentrate has a greater influence on the water quality than in Scenarios 1, but where the $D_m$ is reduced due to the higher overall discharge flow (*i.e.*, compared to Scenarios 2 and 3). The Davidson ocean condition was used as it represents the worst-case dilution for this flow scenario.
5. **Moderate Secondary effluent Flow (*new scenario*):** conditions with a relatively moderate secondary effluent flow of 8 mgd when the GWR Concentrate has a greater influence on the water quality than in Scenario 1, but where the ocean dilution is reduced due to the higher overall discharge flow (*i.e.*, compared to Scenarios 2 through 4). The Davidson ocean condition was used as it represents the worst-case dilution for this flow scenario.

The updated $D_m$ values for these five discharge scenarios are provided in Table 5. Similar to the modeling for the MPWSP and Variant Project, the impact of using 130 open ports was a slight increase (approximately 4%) in the amount of dilution associated with the ocean mixing for the GWR Project discharge scenarios. This confirms that previously modeled GWR Project discharge scenarios included in Trussell 2015a were conservative (*i.e.* the previous analysis slightly over-estimated the ZID concentration for the Ocean Plan constituents).

**Table 5 – Updated minimum probable dilution ($D_m$) values for select MPWSP discharge scenarios**

| No. | Discharge Scenario (Ocean Condition) | Discharge flows (mgd) | | | Previously Reported $D_m$ (120 ports)[a] | Updated $D_m$ (130 ports) |
|---|---|---|---|---|---|---|
| | | Secondary effluent | Hauled Waste | GWR Concentrate | | |
| 1 | Maximum flow with GWR Concentrate with current port configuration (Oceanic) | 23.7 | 0.1 | 0.94 | 137 | 142 |
| 2 | GWR Concentrate with no secondary effluent (Oceanic) | 0 | 0.1 | 0.94 | 523 | 540 |
| 3 | GWR Concentrate with minimum secondary effluent flow (Davidson) | 0.4 | 0.1 | 0.94 | 285 | 295 |
| 4 | GWR Concentrate with low secondary effluent flow (Davidson) | 3 | 0.1 | 0.94 | 201 | 208 |
| 5 | GWR Concentrate with moderate secondary effluent flow (Davidson) | 8 | 0.1 | 0.94 | n/a [b] | 228 |

[a] The previously reported $D_m$ was used in the analysis presented in Trussell 2015a, and was performed with 120 open ports on the outfall.
[b] Not applicable, as Discharge Scenarios 5, with 8 mgd of secondary effluent flow, was not previously modeled.

The $D_m$ values reported in Table 5 were used to assess Ocean Plan compliance for GWR Project Scenarios 1 through 5 using the same methodology and water quality assumptions previously described (Trussell, 2015a). For the updated scenarios (GWR Project Scenarios 1 through 4), the changes to the underlying modeling parameters increased the amount of dilution from ocean mixing. Thus, as previously shown, none of the GWR Project scenarios resulted in an estimated exceedance of the Ocean Plan objectives. For the new scenario (GWR Project Scenario 5), it was estimated that none of the Ocean Plan objectives would be exceeded. Tables with the estimated Ocean Plan constituent concentrations at the edge of the ZID for the GWR Project discharge Scenarios 1 through 5 are provided in Appendix B as concentrations (Table A3) and as a percentage of the Ocean Plan objective (Table A4).

# 3 Conclusions

Additional modeling of the ocean discharges of various scenarios for the MPWSP, Variant Project, and GWR project were performed, including updating previous modeling to reflect changes in the baseline assumptions and key discharge scenarios that were absent from the previous analyses. Two primary conclusions can be drawn from these efforts: (1) all conclusions from the previously modeled discharge conditions remain the same, and (2) ammonia was identified as a potential exceedance for both the MPWSP and the Variant Project when the Desal Brine is discharged with a moderate flow of secondary effluent.

For the updated scenarios, three changes were made with respect to modeling of the ocean discharge: (1) there are currently 130 open discharge ports, which is more than the 120 ports used in the previous analysis; (2) for the MPWSP and Variant Project scenarios, the hauled waste flow was added; and (3) for the Variant Project scenarios, a GWR Concentrate flow 0.94 mgd was used instead of 0.73 mgd. In all cases, the impact of making these changes to the ocean mixing was minor and resulted in slightly greater dilution of the ocean discharges and thus slightly lower concentrations of constituents at the edge of the ZID. These changes were minimal and do not alter the previous conclusions.

Results from the newly modeled scenarios have implications with respect to Ocean Plan compliance. Previously, two types of exceedance were identified: (1) exceedance of PCBs for discharges with a high fraction of Desal Brine flow, and (2) exceedance of several parameters (ammonia, chlordane, DDT, PCBs, TCDD equivalents, and toxaphene) when discharging Desal Brine and GWR Concentrate with little or no secondary effluent. In this most recent analysis, a third type of exceedance was identified—when the discharge contains both the Desal Brine and a moderate secondary effluent flow there may be an exceedance of the Ocean Plan 6-month median objective for ammonia. This type of exceedance was shown for both the MPWSP (Scenario 2) and the Variant Projects (Scenarios 2 and 4) and is a result of the combination of having high ammonia in the treated wastewater with the high salinity (i.e., higher density) of the Desal Brine.

As previously shown, ammonia is not an issue when discharging secondary effluent and GWR Concentrate without Desal Brine, or when the dense Desal Brine[2] is discharged with sufficient secondary effluent, such that the combined discharge results in a rising plume with relatively

[2] Compared to the ambient seawater (33,000 to 34,000 mg/L of TDS), the Desal Brine is denser (~57,500 mg/L of TDS) and when discharged on its own would sink, whereas the secondary effluent (~1,000 mg/L of TDS) and GWR Concentrate (~5,000 mg/L) are relatively light and would rise when discharged. In the combined discharge, the secondary effluent and GWR Concentrate would dilute the salinity of the desalination brine and thus reduce the density. With sufficient dilution, the combined discharge would be less dense than the ambient ocean water, resulting in a rising plume with more dilution in the ZID.

high ocean mixing in the ZID. This potential Ocean Plan exceedance emerges when there is *not* sufficient secondary effluent to dilute the Desal Brine, and thus the combined discharge is denser than the ambient seawater. This negatively buoyant discharge sinks, resulting in relatively low mixing in the ZID. Similarly, as previously shown, ammonia is not an issue when the Desal Brine is discharged with a low secondary effluent flow, where even though there is relatively low ocean mixing in the ZID, the ammonia concentration in the discharge is less because the secondary effluent is a smaller fraction of the overall combined discharge. The worst-case scenario occurs near the point where the Desal Brine is discharged with the highest flow of secondary effluent that still results in a sinking plume. This secondary effluent flow ends up being a moderate flow: approximately 9 mgd when combined with the Desal Brine from the MPWSP or 5.3 mgd of Desal Brine in the case of the Variant Project.

It should be noted that ammonia was already identified as a potential exceedance (along with several other constituents) when the Desal Brine is discharged with the GWR Concentrate with little or no secondary effluent; however, as illustrated by the Variant Scenario 4, these exceedances also apply when there is a moderate flow of secondary effluent (approximately 5.3 mgd).

Dear Dr. Williams,

Please find attached the Excel® spreadsheet containing results of the latest round of dilution analyses for effluent discharged through the Monterey Regional Water Pollution Control Agency's ocean outfall. The method used in the Visual Plumes (VP) model is capable of handling slightly negatively buoyant conditions and produces reasonable results. In addition, the VP model results are conservative for the slightly negatively buoyant scenarios in that the VP predicted dilution ratios are lower than those obtained from the semi-empirical method. Therefore, the semi-empirical method was not used for all slightly negatively buoyant scenarios.

Please feel free to contact me if you have any questions.

| Toxaphene | ug/L | 2.1E-04 | 7.5E-05 | 1.6E-04 | 35% | 74% |
| Trichloroethylene | ug/L | 27 | <0.050 | <0.032 | <0.2% | <0.1% |
| 1,1,2-Trichloroethane | ug/L | 9.4 | <0.050 | <0.032 | <0.5% | <0.3% |
| 2,4,6-Trichlorophenol | ug/L | 0.29 | <2.0E-04 | <0.0086 | <0.07% | <3.0% |
| Vinyl chloride | ug/L | 36 | <0.028 | <0.022 | <0.08% | <0.06% |

[a] Note that if the percentage as determined by using the MRL was less than 0.01 percent, then a minimum value is shown as "<0.01%" (*e.g.*, if the MRL indicated the value was <0.000001%, for simplicity, it is displayed as <0.01%). Also, shading indicates constituent is expected to be greater than 80 percent (orange shading) or exceed (red shading) the ocean plan objective for that discharge scenario.

[b] Calculating flow-weighted averages for toxicity (acute and chronic) and radioactivity (gross beta and gross alpha) is not appropriate based on the nature of the constituent. These constituents were measured for the secondary effluent and those concentrations would comply with the Ocean Plan objectives.

[c] All observed values from all data sources were below the MRL, and the flow-weighted average of the MRLs is higher than the Ocean Plan objective. No compliance conclusions can be drawn for these constituents.

[d] For total chlorine residual, any waste streams containing a free-chlorine residual would be dechlorinated prior to discharge.

**Table A2 – Variant Project list of predicted concentrations of Ocean Plan constituents at the edge of the ZID as a concentration and as a percentage of the Ocean Plan objective [a]**

| Constituent | Units | Ocean Plan Objective | Variant Project Ocean Discharge Scenario | | | | | | | |

[a] Note that if the percentage as determined by using the MRL was less than 0.01 percent, then a minimum value is shown as "<0.01%" (*e.g.*, if the MRL indicated the value was <0.000001%, for simplicity, it is displayed as <0.01%). Also, Shading indicates constituent is expected to be greater than 80 percent (orange shading) or exceed (red shading) the ocean plan objective for that discharge scenario.

[b] Calculating flow-weighted averages for toxicity (acute and chronic) and radioactivity (gross beta and gross alpha) is not appropriate based on the nature of the constituent. These constituents were measured individually for the secondary effluent and GWR concentrate, and these individual concentrations would comply with the Ocean Plan objectives.

[c] All observed values from all data sources were below the MRL, and the flow-weighted average of the MRLs is higher than the Ocean Plan objective. No compliance conclusions can be drawn for these constituents.

[d] For total chlorine residual, any waste streams containing a free-chlorine residual would be dechlorinated prior to discharge.

**Table A3 – GWR Project complete list of predicted concentrations of Ocean Plan constituents at the edge of the ZID for updated scenarios**

| Constituent | Units | Ocean Plan Objective | Estimated Concentration at Edge of ZID by Discharge Scenario | | | | |

[a] Calculating flow-weighted averages for toxicity (acute and chronic) and radioactivity (gross beta and gross alpha) is not appropriate based on the nature of these constituents. These constituents were measured individually for the secondary effluent and RO concentrate, and these individual concentrations would comply with the Ocean Plan objectives.

[b] All observed values from all data sources were below the MRL, and the flow-weighted average of the MRLs is higher than the Ocean Plan objective. No compliance conclusions can be drawn for these constituents.

[c] For total chlorine residual, any waste streams containing a free-chlorine residual would be dechlorinated prior to discharge.

**Table A4 – GWR Project complete list of predicted concentrations of Ocean Plan constituents at the edge of the ZID as a percentage of the Ocean Plan objective for updated scenarios [a]**

| 2,4,6-Trichlorophenol | ug/L | 0.29 | <5.4% | <0.7% | <1.7% | <3.3% | <3.3% |
| Vinyl chloride | ug/L | 36 | <0.01% | <0.01% | <0.01% | <0.01% | <0.01% |

[a] Note that if the percentage as determined by using the MRL was less than 0.01 percent, then a minimum value is shown as "<0.01%" (*e.g.*, if the MRL indicated the value was <0.000001%, for simplicity, it is displayed as <0.01%).

[b] Calculating flow-weighted averages for toxicity (acute and chronic) and radioactivity (gross beta and gross alpha) is not appropriate based on the nature of these constituents. These constituents were measured individually for the secondary effluent and RO concentrate, and these individual concentrations would comply with the Ocean Plan objectives.

[c] All observed values from all data sources were below the MRL, and the flow-weighted average of the MRLs is higher than the Ocean Plan objective. No compliance conclusions can be drawn for these constituents.

[d] For total chlorine residual, any waste streams containing a free-chlorine residual would be dechlorinated prior to discharge.

# 1 Introduction

In response to State Water Resources Control Board (SWRCB) Water Rights Orders WR 95-10 and WR 2009-0060, two proposed projects are in development on the Monterey Peninsula to provide potable water to offset pending reductions of Carmel River water diversions: (1) a seawater desalination project known as the **Monterey Peninsula Water Supply Project (“MPWSP”)**, and (2) a groundwater replenishment project known as the **Pure Water Monterey Groundwater Replenishment Project (“GWR Project”)**. The capacity of the MPWSP is dependent on whether the GWR Project is ultimately constructed. For the MPWSP, California American Water (“CalAm”) would build a seawater desalination facility capable of producing 9.6 million gallons per day (mgd) of drinking water. In a variation of that project, known as the **Monterey Peninsula Water Supply Project Variant (“Variant”)**, CalAm would build a smaller desalination facility capable of producing 6.4 mgd of drinking water, and a partnership between the Monterey Peninsula Water Management District (“MPWMD”) and the Monterey Regional Water Pollution Control Agency (“MRWPCA”) would build an advanced water treatment facility (“AWT Facility”) capable of producing up to 3,700 acre-feet per year (AFY) (3.3 mgd)[1] of highly purified recycled water to enable CalAm to extract 3,500 AFY (3.1 mgd) from the Seaside Groundwater Basin for delivery to their customers. The AWT Facility would purify secondary-treated wastewater (*i.e.*, secondary effluent) from MRWPCA’s Regional Treatment Plant (“RTP”), and this highly purified recycled water would be injected into the Seaside Groundwater Basin and later extracted for municipal water supplies. Both the proposed desalination facility and the proposed AWT Facility would employ reverse osmosis (RO) membranes to purify the waters, and as a result, both projects would produce RO concentrate waste streams that would be disposed through the existing MRWPCA ocean outfall: the brine concentrate from the desalination facility (“Desal Brine”), and the RO concentrate from the AWT Facility (“GWR Concentrate”).

The goal of this technical memorandum is to analyze whether the discharges from the proposed projects to the ocean through the existing outfall would impact marine water quality, and thus, human health, marine biological resources, or beneficial uses of the receiving waters. A similar assessment of the GWR Project on its own was previously performed (Trussell Tech, 2015, see Appendix B), and thus this document is focused on the MPWSP and the Variant projects.

## 1.1 Treatment through the Proposed CalAm Desalination Facility

This section describes the proposed treatment train for the MPWSP desalination facility. Seawater from the Monterey Bay would be extracted through subsurface slant wells beneath the ocean floor and piped to a new CalAm-owned desalination facility. This facility would consist of granular media pressure filters, cartridge filters, a two-pass RO membrane system, RO product-water stabilization (for corrosion control), and disinfection (Figure 1). The RO process is expected to recover 42 percent of the influent seawater flow as product water, while the remainder of the concentrated influent water becomes the Desal Brine. The MPWSP product

[1] One million gallons per day is equal to 1,121 acre-feet per year. The AWT Facility would be capable of producing up to 4 mgd of highly-purified recycled water on a daily basis, but production would fluctuate throughout the year, such that the average annual production would be 3.3 mgd (3,700 AFY) in a non-drought year.

water (desalinated water) would be used for municipal drinking water, while the Desal Brine would be blended with available RTP secondary effluent, brine that is trucked and stored at the RTP, and GWR Concentrate (for the Variant project only), before it is discharged to the ocean through the existing MRWPCA ocean outfall. The volume of Desal Brine is dependent on the project size: 13.98 and 8.99 mgd for the MPWSP and Variant projects, respectively.

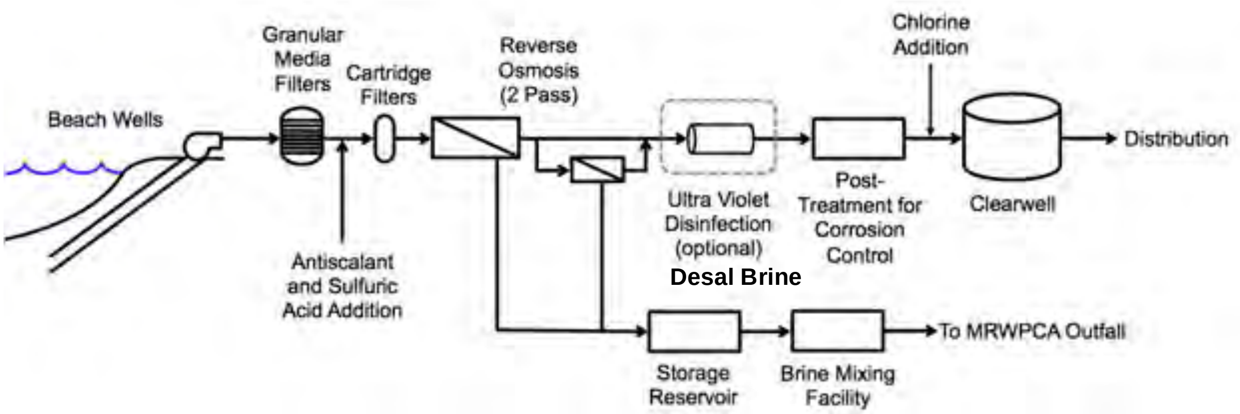

**Figure 1 – Simplified diagram of CalAm desalination facilities**

## 1.2 Treatment through the RTP and Proposed AWT Facilities

The existing MRWPCA RTP treatment process includes screening, primary sedimentation, secondary biological treatment through trickling filters, followed by a solids contactor (*i.e.*, bio-flocculation), and then clarification (Figure 2). Much of the secondary effluent undergoes tertiary treatment (granular media filtration and disinfection) to produce recycled water used for agricultural irrigation. The unused secondary effluent is discharged to the Monterey Bay through the MRWPCA outfall. MRWPCA also accepts trucked brine waste for ocean disposal ("hauled brine"), which is stored in a pond and mixed with secondary effluent for disposal.

The proposed AWT Facility would include several advanced treatment technologies for purifying the secondary effluent: ozone ($O_3$), biologically active filtration (BAF) (this is an optional unit process), membrane filtration (MF), RO, and an advanced oxidation process (AOP) using UV-hydrogen peroxide. MRWPCA and the MPWMD conducted a pilot-scale study of the ozone, MF, and RO elements of the AWT Facility from December 2013 through July 2014, successfully demonstrating the ability of the various treatment processes to produce highly-purified recycled water that complies with the California Groundwater Replenishment Using Recycled Water Regulations (Groundwater Replenishment Regulations),[2] the State Water Resource Control Board's Anti-degradation and Recycled Water Policies,[3] and Central Coast Water Quality Control Plan (Basin Plan)[4] standards, objectives and guidelines for groundwater. Monitoring of the concentrate from the RO was also conducted during the pilot-scale study.

## 1.3 California Ocean Plan

The State Water Resources Control Board 2012 Ocean Plan ("Ocean Plan") sets forth water quality objectives for ocean discharges with the intent of preserving the quality of the ocean water for beneficial uses, including the protection of both human and aquatic ecosystem health (SWRCB, 2012). When municipal wastewater flows are released from an outfall, the wastewater and ocean water undergo rapid mixing due to the momentum and buoyancy of the discharge.[5] The mixing occurring in the rising plume is affected by the buoyancy and momentum of the discharge, a process referred to as initial dilution (NRC, 1993). For rising plumes, the Ocean Plan defines the initial dilution as complete when "the diluting wastewater ceases to rise in the water column and first begins to spread horizontally." For more saline discharges, a sinking plume can form when the mixture of seawater and discharge is denser than the ambient water (also known as a negatively buoyant plume). In the case of negatively buoyant plumes, the Ocean Plan defines the initial dilution as complete when "the momentum induced velocity of the discharge ceases to produce significant mixing of the waste, or the diluting plume reaches a fixed

[5] Municipal wastewater effluent, being effectively fresh water, is less dense than seawater and thus rises (due to buoyancy) while it mixes with ocean water. GWR Concentrate whether by itself or mixed with municipal wastewater effluent is less dense than seawater and also rises (due to buoyancy) while it mixes with ocean water.

distance from the discharge to be specified by the Regional Board, whichever results in the lower estimate for initial dilution."

The Ocean Plan objectives are to be met after the initial dilution of the discharge into the ocean. The initial dilution occurs in an area known as the zone of initial dilution (ZID). The extent of dilution in the ZID is quantified and referred to as the minimum probable initial dilution ($D_m$). The water quality objectives established in the Ocean Plan are adjusted by the $D_m$ to derive the National Pollutant Discharge Elimination System (NPDES) permit limits for a wastewater discharge prior to ocean dilution.

The current MRWPCA wastewater discharge is governed by NPDES permit R3-2014-0013 issued by the Central Coast Regional Water Quality Control Board ("RWQCB"). Because the existing NPDES permit for the MRWPCA ocean outfall must be amended to discharge Desal Brine, comparing future discharge concentrations to the current NPDES permit limits would not be an appropriate metric or threshold for determining whether the proposed projects would have a significant impact on marine water quality. Instead, compliance with the Ocean Plan objectives was selected as an appropriate threshold for determining whether or not the proposed projects would result in a significant impact requiring mitigation. FlowScience, Inc. ("FlowScience") conducted modeling of the ocean discharge for various discharge scenarios involving the proposed projects to determine $D_m$ values for the various discharge scenarios. These ocean modeling results were combined with projected discharge water quality to assess compliance with the Ocean Plan.

## 1.4 Future Ocean Discharges

A summary schematic of the MPWSP and Variant projects is presented in Figure 3. For the MPWSP, 23.58 mgd of ocean water (design capacity) would be treated in the desalination facility; an RO recovery of 42% would lead to an MPWSP Desal Brine flow of 13.98 mgd that would be discharged through the outfall. Secondary effluent from the RTP would also be discharged through the outfall, although the flow would be variable depending on both the influent flow and the proportion being processed through the tertiary treatment system at the Salinas Valley Reclamation Project (SVRP) to produce recycled water for agricultural irrigation. The final discharge component is hauled brine that is trucked to the RTP and blended with secondary effluent prior to being discharged. The maximum anticipated flow of this stream is 0.1 mgd (blend of brine and secondary effluent). These three discharge components (Desal Brine, secondary effluent, and hauled brine) would be mixed at the proposed Brine Mixing Facility prior to ocean discharge.

For the Variant project, 15.93 mgd of ocean water (design capacity) would be pumped to the desalination facility, and an RO recovery of 42% would result in a Variant Desal Brine flow of 8.99 mgd. The Variant would include the GWR Project, which involves the addition of new source waters to the RTP, which could alter the water quality of the secondary effluent produced by the RTP. The secondary effluent in the Variant is referred to as "Variant secondary effluent," and would be different in quality from the MPWSP secondary effluent. Under the GWR Project, a portion of the secondary effluent would be fed to the AWT Facility, and the resultant GWR Concentrate (maximum 0.94 mgd) would be discharged through the outfall. The hauled brine received at the RTP would continue to be blended with secondary effluent prior to discharge, the quality of the blended brine and secondary effluent will change as a result of the change in secondary effluent quality; the hauled brine for the Variant is referred to as "Variant hauled brine."

## 1.5 Objective of Technical Memorandum

Trussell Tech estimated worst-case in-pipe water quality for the various ocean discharge scenarios (*i.e.*, prior to dilution through ocean mixing) for the proposed projects. FlowScience ocean discharge modeling and the results of the water quality analysis were then used to provide an assessment of whether the proposed projects would consistently meet Ocean Plan water quality objectives. The objective of this technical memorandum is to summarize the assumptions, methodology, results and conclusions of the Ocean Plan compliance assessment for the MPWSP and Variant projects.

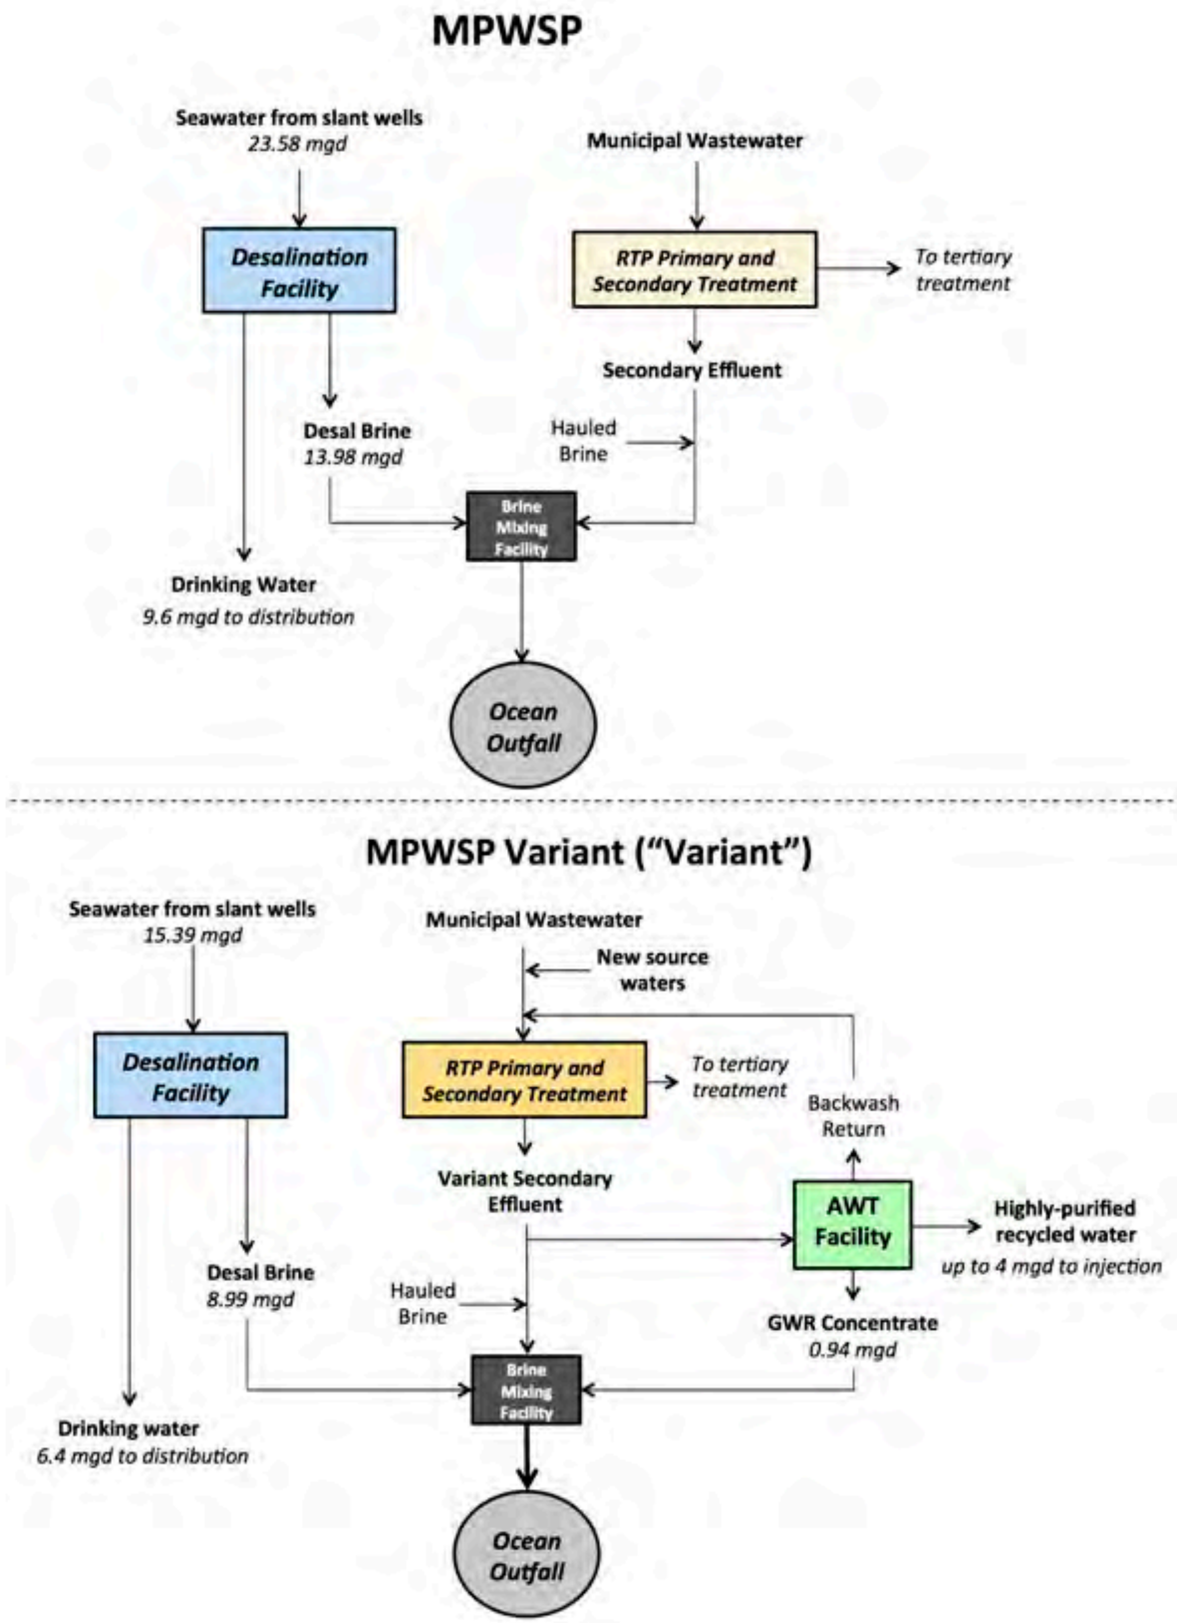

**Figure 3 – Simplified flow schematics for the MPWSP and Variant projects (specified flow rates are at design capacity)**

# 2 Methodology for Ocean Plan Compliance

Water quality data from various sources for the different treatment process influent and waste streams were compiled. Trussell Tech combined these data for different flow scenarios and used ocean modeling results to assess compliance of the different discharge scenarios with the Ocean Plan objectives. This section documents the data sources and provides further detail on the methodology used to perform this analysis. A summary of the methodology is presented in Figure 4.

## 2.1 Methodology for Determination of Discharge Water Quality

As previously discussed, the amounts and combinations of various wastewaters that would be disposed through the MRWPCA Outfall will vary depending on the capacity, seasonal and daily flow characteristics, and extent and timing of implementation of the proposed projects. The discharge components for the MPWSP and Variant are summarized in Table 1.

**Table 1 – Discharge waters Included in each analysis**

| Project | Desal Brine | Secondary Effluent | Variant Secondary Effluent | Hauled Brine | Variant Hauled Brine [a] | GWR Concentrate |
|---|---|---|---|---|---|---|
| MPWSP | ✓ | ✓ | | ✓ | | |
| Variant | ✓ | | ✓ | | ✓ | ✓ |

[a]This is placed in a separate category because it contains some Variant secondary effluent.

Detailed discussions about the methods used to determine the discharge water qualities related to the GWR Project were previously discussed and can be found in Appendix B. This previous analysis included water quality estimates of the secondary effluent and Variant secondary effluent, the hauled brine and Variant hauled brine, and the GWR Concentrate (*i.e.,* all of the discharges except for the Desal Brine). In the previous analysis, Trussell Tech assumed that the highest observed values for the various Ocean Plan constituents within each type of water flowing to and treated at the RTP, including the AWT Facility as applicable, to be the worst-case water quality[6], and these same data were used in the analysis described in this memorandum. Use of these worst-case water quality concentrations ensure that the analysis in both the Appendix B Ocean Plan compliance technical memorandum and this memorandum are conservative related to the Ocean Plan compliance assessment (and thus, the impact analysis for the projects' environmental review processes).

To determine the impact of the MPWSP and Variant Projects, the worst-case water quality of the Desal Brine was estimated using available data for ocean water quality (discussed further below). In all cases, the highest observed concentrations from all data sources were used for the analysis.

[6] The exception to this statement is cyanide. In mid-2011, Monterey Bay Analytical Service (MBAS) began performing the cyanide analysis on the RTP secondary effluent, at which time the reported values increased by an order of magnitude. Because no operational or source water composition changes took place at this time that would result in such an increase, it is reasonable to conclude the increase is an artifact of the change in analysis method and therefore the results were questionable. Therefore, although the cyanide concentrations reported by MBAS are presented, they are not used in the analysis for evaluating compliance with the Ocean Plan objectives for the EIR.

The methodology for determining the water quality of the Desal Brine and secondary effluent is further described in this section (the methodology for all other discharge waters can be found in Appendix B). A summary of which discharge waters are considered for both the MPWSP and Variant, and which data sources were used in the determination of the water quality for each discharge stream is shown in Figure 4.

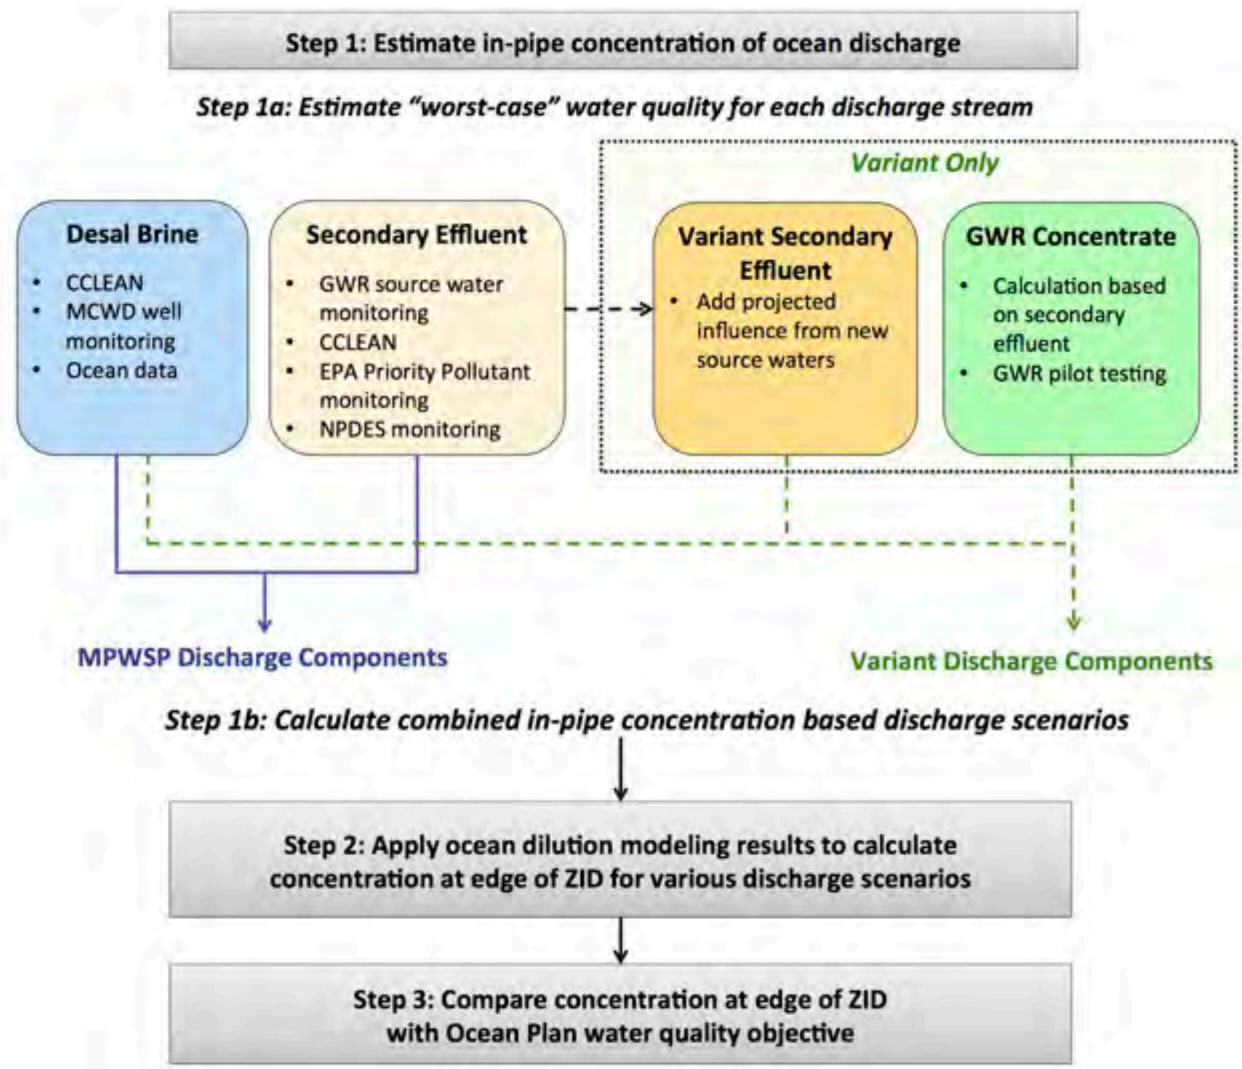

**Figure 4 – Logic flow chart for determination of MPWSP and Variant compliance with Ocean Plan objectives.**

### 2.1.1 Secondary Effluent

For the MPWSP Project, the discharged secondary effluent would not be impacted by additional source waters that would be brought in for the Variant project; therefore, the existing secondary effluent quality was used in the analysis. The following sources of data were considered for selecting an existing secondary effluent concentration for each constituent in the analysis:

- Secondary effluent water quality monitoring conducted for the GWR Project from July 2013 through June 2014
- Historical NPDES compliance data collected semi-annually by MRWPCA (2005-2014)

- Historical Priority Pollutant data collected annually by MRWPCA (2004-2014)
- Data collected by the Central Coast Long-Term Environmental Assessment Network (CCLEAN) (2008-2013)

The existing secondary effluent concentration for each constituent selected for the analysis was the maximum reported value from the above sources. In cases where the analysis of a constituent could not be quantified or it was not detected, the result is reported as less than the Method Reporting Limit (<MRL).[7] Because the actual concentration could be any value equal to or less than the MRL, the conservative approach is to use the value of the MRL in the flow-weighting calculations. In some cases, constituents were not detected ("ND") in any of the source waters; in this case, the values are reported as ND(<X), where X is the MRL. For some non-detected constituents, the MRL exceeds the Ocean Plan objective, and thus no compliance determination can be made[8]. A detailed discussion of the cases where a constituent was reported as less than the MRL is included in the previous technical memorandum in Appendix B.

### 2.1.2 Desal Brine

Only limited data were available for characterizing the Desal Brine water quality. Trussell Tech used the following three sources of data for the Desal Brine water quality assessment:

- Data generated by the CCLEAN program (2008-2013) for samples collected in the Monterey Bay (provided by Asavari Devadiga of ESA via e-mail on November 12, 2014).
- Water quality data collected quarterly in 2009 from a Marina Coast Water District (MCWD) monitoring well (DMW-2)
- Ocean monitoring data for copper and silver from outside the Golden Gate Bridge, collected sporadically from 1993 to 2013, and provided by Dane Hardin of Applied Marine Sciences (transmitted via e-mail on December 29, 2014).

With the exception of copper and silver, the maximum value observed in any of the data sources was assumed to be the "worst-case" water quality for the raw seawater feeding the desalination facility. For copper and silver, each was detected in one sample in the MCWD monitoring well data at an uncharacteristically high concentration (all other samples for the MCWD monitoring program were below detection), and issues related to well sampling technique are suspected (*e.g.*, inadequate flushing). Thus, the ocean monitoring data provided by Dane Hardin was used instead of the MCWD data, as it was considered to be more representative. A Desal Brine concentration was conservatively estimated for each constituent by using a concentration factor

---

[7] The lowest amount of an analyte in a sample that can be quantitatively determined with stated, acceptable precision and accuracy under stated analytical conditions (*i.e*., the lower limit of quantitation). Therefore, acceptable quality control and quality assurance procedures are calibrated to the MRL, or lower. To take into account day-to-day fluctuations in instrument sensitivity, analyst performance, and other factors, the MRL is established at three times the Method Detection Limit (or greater). The Method Detection Limit is the minimum concentration of a substance that can be measured and reported with 99% confidence that the analyte concentration is greater than zero. (40 Code of Federal Regulations Section136 Appendix B).

[8] This phenomenon is common in the implementation of the Ocean Plan where for some constituents, suitable analytical methods are not capable of measuring low enough to quantify the minimum toxicologically relevant concentrations. For these constituents, a discharge is considered compliant if the monitoring results are less than the MRL.

of 1.73, which was calculated assuming complete constituent rejection and a 42 percent recovery through the seawater RO membranes.

Data limitations were such that no data were available for several Ocean Plan constituents. For constituents that lacked Desal Brine data, a concentration of zero was assumed for the analysis, such that the partial influence of the other discharge streams could still be assessed. Thus, a complete "worst-case" assessment for these constituents was not possible. A list of Ocean Plan constituents for which no Desal Brine or seawater data were available is provided in Appendix A, Table A1.

### 2.1.3 Combined Ocean Discharge Concentrations

Having calculated the worst-case future concentrations for each of the possible discharge components, the combined concentration prior to discharge was determined as a flow-weighted average of the contributions of each of the discharge components appropriate for the MPWSP and Variant (see Figure 4).

## 2.2 Ocean Modeling Methodology

In order to determine Ocean Plan compliance, Trussell Tech used the following information: (1) the in-pipe (*i.e.*, pre-ocean dilution) concentration of a constituent ($C_{\text{in-pipe}}$) that was developed as discussed in the previous section, (2) the minimum probable dilution for the ocean mixing ($D_m$) for the discharge flow scenarios that were modeled by FlowScience (FlowScience, 2014a and 2014b), and (3) the background concentration of the constituent in the ocean ($C_{\text{Background}}$) that is specified in the Table 3 of the Ocean Plan (SWRCB, 2012). With this information the concentration at the edge of the zone of initial dilution ($C_{ZID}$) was calculated using the following equation:

$$C_{ZID} = \frac{C_{\text{In-pipe}} + D_m * C_{\text{Background}}}{1 + D_m} \quad (1)$$

The $C_{ZID}$ was then compared to the Ocean Plan water quality objectives[9] in Table 1 of the Ocean Plan (SWRCB, 2012). For each discharge scenario, if the $C_{ZID}$ was below the Ocean Plan objective, then it was assumed that the discharge would comply with the Ocean Plan. However, if the $C_{ZID}$ exceeds the Ocean Plan objective, then it was concluded that the discharge scenario could violate the Ocean Plan objective. Note that this approach could not be applied for some constituents (*e.g.*, acute toxicity, chronic toxicity, and radioactivity[10]).

---

[9] Note that the Ocean Plan (see Ocean Plan Table 2) also defines effluent limitations for oil and grease, suspended solids, settable solids, turbidity, and pH; however, it was not necessary to evaluate these parameters in this assessment. If necessary, the pH of the water would be adjusted to be within acceptable limits prior to discharge. Oil and grease, suspended solids, settable solids, and turbidity do not need to be considered in this analysis as the GWR Concentrate would be significantly better than the secondary effluent with regards to these parameters. Prior to the AWT Facility RO treatment process, the process flow would be treated by MF, which will reduce these parameters, and the waste stream from the MF will be returned to RTP headworks.

[10] Calculating flow-weighted averages for toxicity (acute and chronic) and radioactivity (gross beta and gross alpha) is not appropriate based the nature of the constituent. These constituents were measured individually for the secondary effluent and GWR Concentrate, and these individual concentrations would comply with the Ocean Plan

FlowScience performed modeling of a limited number of discharge scenarios for the MPWSP and Variant that include combinations of Desal Brine, secondary effluent, GWR Concentrate, and hauled brine (FlowScience, 2014a and 2014b). All scenarios assume the maximum flow rates for the GWR Concentrate, Desal Brine and hauled brine, which is a conservative assumption in terms of constituent loading and minimum dilution.

### 2.2.1 Ocean Modeling Scenarios

The modeled scenarios are summarized in Tables 2 and 3 for the MPWSP and the Variant projects, respectively. The Variant discharge scenarios that have no Desal Brine (*i.e.* Scenarios 5 through 9) have already been analyzed and found to comply with the Ocean Plan (Trussell Tech 2015, see Appendix B); these scenarios are shown in Table 3 for completeness, but for simplicity, the analysis of these scenarios is not repeated in Section 3.

**Table 2 - Modeled flow scenarios for the MPWSP**

| No. | Discharge Scenario (Ocean Condition) | Discharge flows (mgd) | | |
|---|---|---|---|---|
| | | Secondary effluent | Desal Brine | Hauled brine [a] |
| 1 | RTP design capacity without Desal Brine | 29.6 | 0 | 0.1 |
| 2 | Desal Brine with no secondary effluent | 0 | 13.98 | 0.1 |
| 3 | Desal Brine with low secondary effluent | 2 | 13.98 | 0.1 |
| 4 | Desal Brine with high secondary effluent [b] | 19.68 | 13.98 | 0.1 |

[a] Hauled brine was not included in the modeling of MPWSP flow scenarios; however, the change in both flow and TDS from the addition of hauled brine is less then 1% and thus is expected to have a negligible impact on the modeled $D_m$.

[b] Note that RTP wastewater flows have been declining in recent years as a result of water conservation; while 19.68 mgd is higher than current RTP wastewater flows, this is expected to be a conservative scenario with respect to ocean modeling, compared to using the current wastewater flows of 16 to 18 mgd.

**MPWSP Flow Scenarios:**

(1) **RTP design capacity without Desal Brine**: Design flow for the RTP, with no discharge of Desal Brine. This scenario could occur if the RTP facility was operated at the peak dry weather flow and the desalination facility was offline. This scenario is similar to discharge conditions used as the basis for the current MRWPCA NPDES discharge permit.

(2) **Desal Brine with no secondary effluent:** The maximum influence of the Desal Brine on the overall discharge (*i.e.*, no secondary effluent discharged). This scenario would be representative of conditions when demand for recycled water is highest (*e.g.*, during summer months), and all of the RTP secondary effluent is recycled through the SVRP for agricultural irrigation.

---

objectives. No radioactivity or toxicity data were available for the seawater, and thus no determination could be made for these parameters for scenarios involving the Desal Brine.

(3) **Desal Brine with low secondary effluent:** Desal Brine discharged with a relatively low amount of secondary effluent, resulting in a negatively buoyant plume. This scenario represents times when demand for recycled water is high, but there is excess secondary effluent that is discharged to the ocean.

(4) **Desal Brine with high secondary effluent:** Desal Brine discharged with a relatively high amount of secondary effluent, resulting in a positively buoyant plume. This scenario would be representative of conditions when demand for recycled water is lowest (*e.g.*, during winter months), and the SVRP is not operational.

**Table 3 – Modeled flow scenarios for the Variant project**

| No. | Discharge Scenario (Ocean Condition) | Discharge Flows (mgd) | | | |
|---|---|---|---|---|---|
| | | Secondary Effluent | Desal Brine | GWR Concentrate | Hauled Brine [a] |
| 1 | Desal Brine only | 0 | 8.99 | 0 | 0.1 |
| 2 | Desal Brine with high secondary effluent [b] | 19.68 | 8.99 | 0 | 0.1 |
| 3 | Desal Brine with GWR Concentrate and high secondary effluent | 15.92 | 8.99 | 0.94[c] | 0.1 |
| 4 | Desal Brine with GWR Concentrate and no secondary effluent | 0 | 8.99 | 0.94[c] | 0.1 |
| 5 | RTP design capacity with GWR Concentrate [d] | 24.7 | 0 | 0.94 | 0.1 |
| 6 | RTP capacity with GWR Concentrate with current port configuration [d] | 23.7 | 0 | 0.94 | 0.1 |
| 7 | Minimum secondary effluent flow with GWR Concentrate [d] | 0 | 0 | 0.94 | 0.1 |
| 8 | Minimum secondary effluent flow with GWR Concentrate during Davidson oceanic conditions [d] | 0.4 | 0 | 0.94 | 0.1 |
| 9 | Moderate secondary effluent flow with GWR concentrate [d] | 3 | 0 | 0.94 | 0.1 |

[a] Hauled brine was not included in the modeling of Variant scenarios involving discharge of desalination brine. However, the change in both flow and TDS from the addition of hauled brine is less than 1% and thus is expected to have a negligible impact on the modeled $D_m$.
[b] Note that RTP wastewater flows are have been declining in recent years as a result of conservation; while 19.68 mgd is higher than current RTP wastewater flows, this is expected to be a conservative scenario with respect to ocean modeling, compared to using the current wastewater flows of 16 to 18 mgd.
[c] The actual modeled GWR Concentrate flow was 0.73 mgd (based on an older design for the AWT Facility). This change is not expected to have a significant impact on the modeled $D_m$. Future updates to modeling results would include the updated GWR Concentrate flow of 0.94 mgd.
[d] Scenarios 5 through 9 were analyzed as part of a previous analysis (see Appendix B), and based on the documented assumptions, the GWR Concentrate would comply with the Ocean Plan objectives; therefore, these scenarios are not discussed further in this memorandum.

**Variant Project Flow Scenarios:**

(1) **Desal Brine only:** Desal Brine discharged without secondary effluent or GWR Concentrate. This scenario would be representative of conditions when the smaller (6.4 mgd) desalination facility is in operation, but the AWT Facility is not operating

(*e.g.*, offline for maintenance), and all of the secondary effluent is recycled through the SVRP (*e.g.*, during high irrigation water demand summer months).

(2) **Desal Brine with high secondary effluent:** Desal Brine discharged with a relatively high flow of secondary effluent, resulting in a positively buoyant plume. This scenario would be representative of conditions when demand for recycled water is lowest (*e.g.*, during winter months), and neither the SVRP nor the AWT Facility are operational.

(3) **Desal Brine with GWR Concentrate and high secondary effluent:** Desal Brine discharged with GWR Concentrate and a relatively high flow of secondary effluent. The reduction of secondary effluent flow between Scenario 2 and this scenario is a result of the AWT Facility operation. This would be a typical discharge scenario when there is no demand for tertiary recycled water (*e.g.*, during winter months).

(4) **Desal Brine with GWR Concentrate and no secondary effluent:** Desal Brine discharge with GWR Concentrate and no secondary effluent. This scenario would be representative of the condition where both the desalination facility and the AWT Facility are in operation, and there is the highest demand for recycled water through the SVRP (*e.g.*, during summer months).

(5-9) **Variant conditions with no Desal Brine contribution**: These scenarios represent a range of conditions that would exist when the CalAm desalination facilities were offline for any reason. These conditions were previously evaluated (Trussell Tech, 2015) and thus are not discussed further in this technical memorandum.

The discharge scenarios presented in Tables 2 and 3 are the most representative scenarios that have been modeled for the proposed projects, however, it should be noted that some key discharge scenarios have yet to be modeled. Specifically, a discharge scenario where a moderate secondary effluent flow (*e.g.*, between 4 and 10 mgd) is discharged along with the Desal Brine, such that the combined discharge still results in a negatively buoyant plume[11]. Therefore, the results presented in Section 3 should be viewed as partial findings. A separate technical memorandum is in the process of being prepared to amend the work in this report to include the analysis recommended in this paragraph. It is anticipated for completion by late March 2015.

### 2.2.2 Ocean Modeling Assumptions

FlowScience documented the modeling assumptions and results in two technical memoranda (FlowScience, 2014a and 2014b). The modeling assumptions were specific to the oceanic condition: Davidson (November to March), Upwelling (April to August), and Oceanic (September to October)[12]. In order to conservatively demonstrate Ocean Plan compliance, the

[11] This scenario has the potential to be the "worst-case" discharge scenario, because it represents the case where there is a confluence of higher contaminant loading from the secondary effluent with the lower ocean mixing dilution that results from negatively buoyant discharge plumes. For cases where there is little or no secondary effluent discharged along with the Desal Brine, the ocean mixing is still low but, in general, there is a lower contaminant load. Conversely, in cases where there is a relatively high secondary effluent discharge flow, the contaminant loading is higher, but the Desal Brine salinity is diluted to the point that the discharge plume is positively buoyant and greater mixing is achieved within the ZID.

[12] Note that these ranges assign the transitional months to the ocean condition that is typically more restrictive at relevant discharge flows.

lowest $D_m$ from the applicable ocean conditions was used for each flow scenario. It should also be noted that for all scenarios except one[13], the ocean modeling was performed assuming 120 of the 172 diffuser ports were open. After the modeling was performed, it was discovered that there are actually 130 open ports. An increase in the number of ports decreases the port discharge velocity, which would tend to increase the dilution; however, this is not always the case[14]. Ocean modeling using 130 open ports will be included in the aforementioned analysis that is anticipated for completion by late March 2015.

For negatively buoyant plumes, FlowScience modeled the ocean mixing using two methods: (1) a Semi-Empirical Analysis method, and (2) EPA's Visual Plume method. While results were provided from both methods, FlowScience indicated that there is greater confidence in Semi-Empirical Analysis results for negatively buoyant plumes. Thus, the Semi-Empirical Analysis results were used in this analysis for the discharges with a negatively buoyant plume.

# 3 Ocean Plan Compliance Results

## 3.1 Water Quality of Combined Discharge

As described above, the first step in the Ocean Plan compliance analysis was to estimate the worst-case water quality for the future wastewater discharge components (*i.e.*, Desal Brine, Secondary Effluent, Hauled Brine and GWR Concentrate). The estimated water quality for each type of discharge is provided in Table 4. Specific assumptions and data sources for each constituent are documented in the Table 4 footnotes.

**Table 4 – Estimated worst-case water quality for the various discharge waters**

| Constituent | Units | Desal Brine | Secondary Effluent | | Hauled Brine | | GWR Concentrate | Footnotes |
|---|---|---|---|---|---|---|---|---|
| | | | *MPWSP* | *Variant* | *MPWSP* | *Variant* | | |

**Table 4 Footnotes:**

***MPWSP Secondary Effluent and Hauled Brine***

[1] The value reported is based on MRWPCA historical data.
[2] The value reported is based on secondary effluent data collected during the GWR Project source water monitoring programs (not impacted by the proposed new source waters), and are representative of future water quality under the MPWSP scenario.
[3] The MRL provided represents the limit from NPDES monitoring data for secondary effluent and hauled waste. In cases where constituents had varying MRLs, where in general, the lowest MRL is reported.
[4] RTP effluent value presented based on CCLEAN data.

***Total Chlorine Residual***

[5] For all waters, it is assumed that dechlorination will be provided such that the total chlorine residual will be below detection.

***Variant Secondary Effluent and Hauled Brine***

[6] Existing RTP effluent exceeds concentrations observed in other proposed source waters; the value reported is the existing secondary effluent value.
[7] The proposed new source waters may increase the secondary effluent concentration; the value reported is based on predicted source water blends.
[8] RTP effluent value is based on CCLEAN data; no other source waters were considered due to MRL differences.
[9] MRL provided represents the maximum flow-weighted MRL based on the blend of source waters.
[10] The only water with a detected concentration was the RTP effluent, however the flow-weighted concentration increases due to higher MRLs for the proposed new source waters.
[11] Additional source water data are not available; the reported value is for RTP effluent.
[12] Calculation of the flow-weighted concentration was not feasible due to constituent and the maximum observed value reported.
[13] Agricultural Wash Water data are based on an aerated sample, instead of a raw water sample.
[14] This value in the Ocean Plan is an aggregate of several congeners or compounds. Per the approach described in the Ocean Plan, for cases where the individual congeners/compounds were less than the MRL, a value of 0 is assumed in calculating the aggregate value, as the MRLs span different orders of magnitude.

***GWR Concentrate Data***

[15] The value presented represents a calculated value assuming no removal prior to RO, complete rejection through RO membrane, and an 81% RO recovery.
[16] The value represents the maximum value observed during the pilot testing study.
[17] The calculated value for the AWT Facility data (described in note 15) was not used in the analysis because it was not considered representative. It is expected that the value would increase as a result of treatment through the AWT Facility (*e.g.* formation of N-Nitrosodimethylamine as a disinfection by-product), or that it will not concentrate linearly through the RO (*e.g.* toxicity and radioactivity).
[18] The MRL provided represents the limit from the source water and pilot testing monitoring programs.
[19] The value presented represents a calculated value assuming 20% removal through primary and secondary treatment, 70% and 90% removal through ozone for DDT and dieldrin, respectively (based on Oram, 2008), complete rejection through the RO membrane, and an 81% RO recovery. The assumed RTP concentrations for Dieldrin and DDT do not include contributions from the agricultural drainage waters. This is because in all but one flow scenario (Scenario 4, described later), either the agricultural drainage waters are not being brought into the RTP because there is sufficient water from other sources (*e.g.* during wet and normal precipitation years), or the RTP effluent is not being discharged to the outfall (*e.g.*, summer months). In this one scenario (Scenario 4), there is a minimal discharge of secondary effluent to the ocean during a drought year under Davidson ocean conditions; for

this flow scenario only, different concentrations are assumed for the RTP effluent. DDT and dieldrin concentrations of 0.022 µg/L and 0.0056 µg/L were used for Scenario 4 in the analysis.

***Cyanide Data***
[20] In mid-2011, MBAS began performing the cyanide analysis on the RTP effluent, at which time the reported values increased by an order of magnitude. Because no operational or source water composition changes took place at this time that would result in such an increase, it is reasonable to conclude the increase is an artifact of the change in analysis method and therefore questionable. Therefore, the cyanide values as measured by MBAS are listed separately from other cyanide values, and the MBAS data were not be used in the analysis for evaluating compliance with the Ocean Plan objectives for the EIR.

***Desal Brine Data***
[21] Reported Desal Brine value is based on data from 2009 monitoring data from a Marina Coast Water District monitoring well, adjusted by assuming completed contaminant rejection through the seawater RO membranes with an overall 42% recovery.
[22] Reported Desal Brine value is based on data ocean data from the Golden Gate area provided by Dane Hardin (transmitted via e-mail on December 29, 2014).
[23] Reported Desal Brine value presented based on CCLEAN data.
[24] No data were available to estimate the Desal Brine concentration.

## 3.2 Ocean Modeling Results

The predicted minimum probable dilution ($D_m$) for each discharge scenario is presented in Tables 5 and 6. For discharge scenarios that were modeled with more than one oceanic condition, the lowest $D_m$ (*i.e.*, most conservative) is reported in the tables below. For the MPWSP, the flow scenarios in which little or no secondary effluent was discharged (Scenarios 2 and 3) resulted in lowest $D_m$ values as a result of the discharge plume being negatively buoyant. At higher secondary effluent flows, the discharge plume would be positively buoyant, resulting in an increased $D_m$, as evidenced in Scenario 4. The same trend was observed for Variant scenarios.

**Table 5 – Flow scenarios and modeled $D_m$ values used for Ocean Plan compliance analysis for MPWSP**

| No. | Discharge Scenario (Ocean Condition) | Flows (mgd) | | | $D_m$ |
|---|---|---|---|---|---|
| | | Secondary Effluent | Desal Brine | Hauled Brine [a] | |
| 1 | RTP design capacity without Desal Brine | 29.6 | 0 | 0.1 | 145 |
| 2 | Desal Brine with no secondary effluent | 0 | 13.98 | 0.1 | 16 |
| 3 | Desal Brine with low secondary effluent | 2 | 13.98 | 0.1 | 19 |
| 4 | Desal Brine with high secondary effluent | 19.68 | 13.98 | 0.1 | 68 |

[a] Hauled brine was not included in the modeling of MPWSP flow scenarios; however, the change in both flow and TDS from the addition of hauled brine is less than 1% and thus is expected to have a negligible impact on the modeled $D_m$.

**Table 6 – Flow scenarios and modeled $D_m$ values used for Ocean Plan compliance analysis for Variant**

| No. | Discharge Scenario (Ocean Condition) | Flows (mgd) | | | | $D_m$ |
|---|---|---|---|---|---|---|
| | | Variant Secondary Effluent | Desal Brine | GWR Concentrate | Variant Hauled Brine[a] | |
| 1 | Desal Brine only | 0 | 8.99 | 0 | 0.1 | 15 |
| 2 | Desal Brine with high secondary effluent | 19.68 | 8.99 | 0 | 0.1 | 84 |
| 3 | Desal Brine with GWR concentrate and high secondary effluent | 15.92 | 8.99 | 0.94 [b] | 0.1 | 82 |
| 4 | Desal Brine with GWR concentrate and no secondary effluent | 0 | 8.99 | 0.94 [b] | 0.1 | 17 |

[a] Hauled brine was not included in the modeling of Variant scenarios involving discharge of desalination brine. However, the change in both flow and TDS from the addition of hauled brine is less than 1% and thus is expected to have a negligible impact on the modeled $D_m$.
[b] The actual modeled GWR Concentrate flow was 0.73 mgd (based on an older design for the AWT Facility). This change is not expected to have a significant impact on the modeled $D_m$. Updated modeling results will include the correct GWR Concentrate flow of 0.94 mgd.

## 3.3 Ocean Plan Compliance Results

The flow-weighted in-pipe concentration for each constituent was calculated for each modeled discharge scenario using the water quality presented in Table 4 and the discharge flows presented in Tables 2 and 3. The in-pipe concentration was then used to calculate the concentration at the edge of the ZID using the $D_m$ values presented in Tables 5 and 6. The resulting concentrations for each constituent in each scenario were compared to the Ocean Plan objective to assess compliance. The estimated concentrations for the eight flow scenarios (four each for the MPWSP and Variant projects) for all constituents are presented as concentrations at the edge of the ZID (Appendix A, Table A2) and as a percentage of the Ocean Plan objective (Appendix A, Table A3). It was identified that some constituents are estimated to exceed the Ocean Plan objective for some discharge scenarios. A list of the constituents that may be an issue[15] are shown as predicted concentration at the edge of the ZID in Table 7, and as the concentration at the edge of the ZID as a percentage of the Ocean Plan objective in Table 8.

The first issue that was identified is related to polychlorinated biphenyls (PCBs). The maximum concentration of PCBs observed in the ocean water through the CCLEAN program, 1.21 nanograms per liter (ng/L), is already greater than the Ocean Plan objective of 0.019 ng/L (CCLEAN, 2014). Assuming a concentration factor of 1.73 through the desalination facility, a Desal Brine PCB concentration of 2.09 ng/L was calculated. This concentration of Desal Brine PCB would result in Ocean Plan exceedances under several of the MPSWP and Variant scenarios. However, if one puts these data in the context of the existing ambient seawater

[15] Note that aldrin, benzidine, beryllium, 3,3-dichlorobenzidine, heptachlor, heptachlor epoxide, and hexachlorobenzene had high MRLs, such that no compliance conclusions could be drawn for these constituents. This is a typical occurrence for ocean discharges since the MRL is often higher than the ocean plan objective for some constituents.

conditions, the worst-case increase of PCBs for the scenarios described in this memorandum would be a 4.6% increase at the edge of the ZID compared to ambient ocean conditions (*i.e.*, a concentration at the ZID of 1.27 ng/L compared to the ambient levels of 1.21 ng/L). Further, if the median ocean water PCB concentration from CCLEAN was used instead (0.043 ng/L), the assumed Desal Brine concentration would be 0.074 ng/L, and then the only expected scenario with a PCB Ocean Plan exceedance would be for Variant Scenario 4.

**Table 7 – Predicted concentrations at the edge of the ZID for Ocean Plan constituents of concern in the MPWSP and Variant projects**

| Constituent | Units | Ocean Plan Objective | Estimated Concentration at Edge of ZID by Scenario | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|
| | | | MPWSP Project | | | | Variant | | | |
| | | | 1 | 2 | 3 | 4 | 1 | 2 | 3 | 4 |

| Toxaphene | ug/L | 2.1E-04 | 4.9E-05 | 7.9E-05 | 1.0E-04 | 6.8E-05 | 8.5E-05 | 6.2E-05 | 7.4E-05 | 2.6E-04 |

[a] Shading indicates constituent is expected to be greater than 80 percent (orange shading) or exceed (red shading) the ocean plan objective for that discharge scenario.

**Table 8 – Predicted concentrations at the edge of the ZID expressed as percentage of Ocean Plan Objective for constituents of in the MPWSP and Variant projects [a]**

| Constituent | Units | Ocean Plan Objective | Est. Percentage of Ocean Plan objective at Edge of ZID by Scenario | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|
| | | | MPWSP Project | | | | Variant | | | |
| | | | 1 | 2 | 3 | 4 | 1 | 2 | 3 | 4 |
| ***Objectives for protection of marine aquatic life*** | | | | | | | | | | |
| Copper | ug/L | 3 | 69% | 69% | 70% | 69% | 70% | 73% | 75% | 92% |
| Ammonia (as N) – 6-mo median | ug/L | 600 | 42% | 3% | 40% | 52% | 5% | 49% | 59% | 170% |
| ***Objectives for protection of human health - carcinogens*** | | | | | | | | | | |
| Chlordane | ug/L | 2.3E-05 | 22% | 51% | 58% | 32% | 55% | 29% | 35% | 132% |
| DDT | ug/L | 1.7E-04 | 4% | 19% | 18% | 7% | 29% | 7% | 16% | 129% |
| PCBs | ug/L | 1.9E-05 | 24% | 645% | 502% | 96% | 683% | 69% | 81% | 648% |
| TCDD Equivalents | ug/L | 3.9E-09 | 27% | 2% | 25% | 33% | 3% | 32% | 38% | 110% |
| Toxaphene | ug/L | 2.1E-04 | 23% | 38% | 49% | 32% | 41% | 30% | 35% | 125% |

[a] Shading indicates constituent is expected to be greater than 80 percent (orange shading) or exceed (red shading) the ocean plan objective for that discharge scenario.

The second issue identified is for one specific scenario, Variant Scenario 4. Variant Scenario 4 involves the discharge of Desal Brine and GWR concentrate only. The constituents of interest related to this scenario are copper, ammonia, chlordane, DDT, PCBs, TCDD equivalents, and toxaphene. Other than the previously discussed PCBs, ammonia is expected to be the constituent with the highest exceedance, being 1.7 times than the Ocean Plan objective. This scenario is problematic because constituents that have relatively high loadings in the secondary effluent are concentrated in the GWR Concentrate. This scenario assumes the GWR Concentrate flow is much smaller than the Desal Brine flow, such that the resulting discharge plume is negatively buoyant and achieves poor ocean mixing. It is likely that some mitigation strategy would be needed to address these constituents when operating under this discharge scenario. One potential mitigation strategy that has been identified to address this impact is Desal Brine storage. Desal Brine could be stored and released in batches, to take advantage of two phenomena: (1) when the Desal Brine is being stored, there would be an increase in ocean mixing due to the increased buoyancy of the discharge (*i.e.*, the Desal Brine discharge would need to be reduced to the point that the overall discharge is positively buoyant), and (2) when the Desal Brine batch is being released, there would be greater in-pipe dilution of copper, ammonia, chlordane, DDT, TCDD equivalents, and toxaphene (*i.e.* sufficient Desal Brine would need to be released to provide adequate dilution of the constituents of interest).

# 4 Conclusions

The purpose of this analysis was to assess the ability of the MPWSP and Variant Projects to comply with the Ocean Plan objectives. Trussell Tech used a conservative approach to estimate the water qualities of the secondary effluent, GWR Concentrate, Desal Brine and hauled brine for these projects. These water quality data were then combined for various discharge scenarios, and a concentration at the edge of the ZID was calculated for each constituent and scenario. Compliance assessments could not be made for selected constituents, as noted, due to analytical limitations, but this is a typical occurrence for these Ocean Plan constituents. Further, the results presented in this document should be viewed as partial findings, as certain key discharge scenarios were not included in the ocean modeling. Additional analyses are planned for the future to complete this analysis.

Based on the data, assumptions, modeling, and analytical methodology presented in this technical memorandum, the MPWSP and Variant Projects would require mitigation strategies to comply with the Ocean Plan objectives under some discharge scenarios. Specifically, two types of potential issues were identified: (1) PCBs, which are relatively high in the worst-case ocean water samples and were predicted to exceed the Ocean Plan objectives in several scenarios for both the MPWSP and Variant projects, and (2) the Variant discharge scenario where Desal Brine and GWR Concentrate are discharged without secondary effluent were predicted to exceed multiple Ocean Plan objectives, specifically those for ammonia, chlordane, DDT, PCBs, TCDD equivalents, and toxaphene.

[a] Calculating flow-weighted averages for toxicity (acute and chronic) and radioactivity (gross beta and gross alpha) is not appropriate based the nature of the constituent. These constituents were measured individually for the secondary effluent and GWR concentrate, and these individual concentrations would comply with the Ocean Plan objectives.
[b] All observed values from all data sources were below the MRL, and the flow-weighted average of the MRLs is higher than the Ocean Plan objective. No compliance conclusions can be drawn for these constituents.

**Table A3 – Complete list of predicted concentrations at the edge of the ZID expressed as a percentage of Ocean Plan[a]**

[a] Note that if the percentage as determined by using the MRL was less than 0.01 percent, then a minimum value is shown as "<0.01%" (*e.g.*, if the MRL indicated the value was <0.000001%, for simplicity, it is displayed as <0.01%). Also, shading indicates constituent is expected to be greater than 80 percent (orange shading) or exceed (red shading) the ocean plan objective for that discharge scenario.

[b] Calculating flow-weighted averages for toxicity (acute and chronic) and radioactivity (gross beta and gross alpha) is not appropriate based the nature of the constituent. These constituents were measured individually for the secondary effluent and GWR concentrate, and these individual concentrations would comply with the Ocean Plan objectives.

[c] All observed values from all data sources were below the MRL, and the flow-weighted average of the MRLs is higher than the Ocean Plan objective. No compliance conclusions can be drawn for these constituents.

## INTRODUCTION

The Pure Water Monterey Groundwater Replenishment Project is a water supply project that will serve northern Monterey County providing purified water for recharge of a groundwater basin that serves as drinking water supply, and recycled water to augment the existing Castroville Seawater Intrusion Project's crop irrigation supply. The GWR Project would be located within northern Monterey County and would include new facilities located within the unincorporated areas of the Salinas Valley and the cities of Salinas, Marina, Seaside, Monterey, and Pacific Grove.

This report evaluates the potential noise and vibration impacts that could result from implementation of the GWR Project both with regard to temporary impacts during construction and long-term impacts from operation. The report describes the existing noise environment, presents relevant noise and vibration regulations and standards, identifies sensitive receptors to noise and vibration that could be affected by the GWR Project, evaluates the potential effects of construction and operation on these receptors, and identifies mitigation measures as appropriate.

## SETTING

### Fundamentals of Environmental Noise and Vibration

#### *Noise*

Noise may be defined as unwanted sound. Noise is usually objectionable because it is disturbing or annoying. The objectionable nature of sound could be caused by its *pitch* or its *loudness*. *Pitch* is the height or depth of a tone or sound, depending on the relative rapidity (frequency) of the vibrations by which it is produced. Higher pitched signals sound louder to humans than sounds with a lower pitch. *Loudness* is intensity of sound waves combined with the reception characteristics of the ear. Intensity may be compared with the height of an ocean wave in that it is a measure of the amplitude of the sound wave.

In addition to the concepts of pitch and loudness, there are several noise measurement scales which are used to describe noise in a particular location. A *decibel* (*dB*) is a unit of measurement which indicates the relative amplitude of a sound. The zero on the decibel scale is based on the lowest sound level that the healthy, unimpaired human ear can detect. Sound levels in decibels are calculated on a logarithmic basis. An increase of 10 decibels represents a ten-fold increase in acoustic energy, while 20 decibels is 100 times more intense, 30 decibels is 1,000 times more intense, etc. There is a relationship between the subjective noisiness or loudness of a sound and its intensity. Each 10 decibel increase in sound level is perceived as approximately a doubling of loudness over a fairly wide range of intensities. Technical terms are defined in Table 1.

There are several methods of characterizing sound. The most common in California is the *A-weighted sound level (dBA).* This scale gives greater weight to the frequencies of sound to which the human ear is most sensitive. Representative outdoor and indoor noise levels in units of dBA are shown in Table 2. Because sound levels can vary markedly over a short period of time, a method for describing either the average character of the sound or the statistical behavior of the variations must be utilized. Most commonly, environmental sounds are described in terms of an average level that has the same acoustical energy as the summation of all the time-varying events. This *energy-equivalent sound/noise descriptor* is called $L_{eq}$. The most common averaging period is hourly, but $L_{eq}$ can describe any series of noise events of arbitrary duration. The scientific instrument used to measure noise is the sound level meter. Sound level meters can accurately measure environmental noise levels to within about plus or minus 1 dBA. Various computer models are used to predict environmental noise levels from sources, such as roadways and airports. The accuracy of the predicted models depends upon the distance the receptor is from the noise source. Close to the noise source, the models are accurate to within about plus or minus 1 to 2 dBA.

Since the sensitivity to noise increases during the evening and at night -- because excessive noise interferes with the ability to sleep -- 24-hour descriptors have been developed that incorporate artificial noise penalties added to quiet-time noise events. The *Community Noise Equivalent Level* (*CNEL*) is a measure of the cumulative noise exposure in a community, with a 5 dB penalty added to evening (7:00 p.m. - 10:00 p.m.) and a 10 dB addition to nocturnal (10:00 p.m. - 7:00 a.m.) noise levels. The *Day/Night Average Sound Level* ($L_{dn}$) is essentially the same as CNEL, with the exception that the evening time period is dropped and all occurrences during this three-hour period are grouped into the daytime period.

***Vibration***

Ground vibration consists of rapidly fluctuating motions or waves with an average motion of zero. Several different methods are typically used to quantify vibration amplitude. One is the *Peak Particle Velocity (PPV)* and another is the *Root Mean Square (RMS)* velocity. The PPV is defined as the maximum instantaneous positive or negative peak of the vibration wave. The RMS velocity is defined as the average of the squared amplitude of the signal. The PPV and RMS vibration velocity amplitudes are used to evaluate human response to vibration. In this analysis, a PPV descriptor, with units of mm/sec or in/sec, is used to evaluate construction generated vibration for building damage and human complaints. Table 3 displays the reactions of people and the effects on buildings that continuous vibration levels produce. The annoyance levels shown in Table 3 should be interpreted with care since vibration may be found to be annoying at much lower levels than those shown, depending on the level of activity or the sensitivity of the individual. To sensitive individuals, vibrations approaching the threshold of perception can be annoying.

Low-level vibrations frequently cause irritating secondary vibration, such as a slight rattling of windows, doors, or stacked dishes. The rattling sound can give rise to exaggerated vibration complaints, even though there is very little risk of actual structural damage. In high noise environments, which are more prevalent where groundborne vibration approaches perceptible levels, this rattling phenomenon may also be produced by loud airborne environmental noise causing induced vibration in exterior doors and windows.

Construction activities can cause vibration that varies in intensity depending on several factors. The use of pile driving and vibratory compaction equipment typically generates the highest construction related groundborne vibration levels. Because of the impulsive nature of such activities, the use of the PPV descriptor has been routinely used to measure and assess groundborne vibration and almost exclusively to assess the potential of vibration to induce structural damage and the degree of annoyance for humans.

The two primary concerns with construction-induced vibration, the potential to damage a structure and the potential to interfere with the enjoyment of life, are evaluated against different vibration limits. Studies have shown that the threshold of perception for average persons is in the range of 0.008 to 0.012 in/sec PPV. Human perception to vibration varies with the individual and is a function of physical setting and the type of vibration. Persons exposed to elevated ambient vibration levels such as people in an urban environment may tolerate a higher vibration level.

Structural damage can be classified as cosmetic only, such as minor cracking of building elements, or may threaten the integrity of the building. Safe vibration limits that can be applied to assess the potential for damaging a structure vary by researcher and there is no general consensus as to what amount of vibration may pose a threat for structural damage to the building. Construction-induced vibration that can be detrimental to the building is very rare and has only been observed in instances where the structure is at a high state of disrepair and the construction activity occurs immediately adjacent to the structure.

**TABLE 1 Definitions of Acoustical Terms Used in this Report**

| **Term** | **Definition** |
|---|---|
| Decibel, dB | A unit describing, the amplitude of sound, equal to 20 times the logarithm to the base 10 of the ratio of the pressure of the sound measured to the reference pressure. The reference pressure for air is 20 micro Pascals. |
| Sound Pressure Level | Sound pressure is the sound force per unit area, usually expressed in micro Pascals (or 20 micro Newtons per square meter), where 1 Pascal is the pressure resulting from a force of 1 Newton exerted over an area of 1 square meter. The sound pressure level is expressed in decibels as 20 times the logarithm to the base 10 of the ratio between the pressures exerted by the sound to a reference sound pressure (e.g., 20 micro Pascals). Sound pressure level is the quantity that is directly measured by a sound level meter. |
| Frequency, Hz | The number of complete pressure fluctuations per second above and below atmospheric pressure. Normal human hearing is between 20 Hz and 20,000 Hz. Infrasonic sound are below 20 Hz and Ultrasonic sounds are above 20,000 Hz. |
| A-Weighted Sound Level, dBA | The sound pressure level in decibels as measured on a sound level meter using the A-weighting filter network. The A-weighting filter de-emphasizes the very low and very high frequency components of the sound in a manner similar to the frequency response of the human ear and correlates well with subjective reactions to noise. |
| Equivalent Noise Level, $L_{eq}$ | The average A-weighted noise level during the measurement period. |
| $L_{max}$, $L_{min}$ | The maximum and minimum A-weighted noise level during the measurement period. |
| $L_{01}$, $L_{10}$, $L_{50}$, $L_{90}$ | The A-weighted noise levels that are exceeded 1%, 10%, 50%, and 90% of the time during the measurement period. |
| Day/Night Noise Level, $L_{dn}$ or DNL | The average A-weighted noise level during a 24-hour day, obtained after addition of 10 decibels to levels measured in the night between 10:00 p.m. and 7:00 a.m. |
| Community Noise Equivalent Level, CNEL | The average A-weighted noise level during a 24-hour day, obtained after addition of 5 decibels in the evening from 7:00 p.m. to 10:00 p.m. and after addition of 10 decibels to sound levels measured in the night between 10:00 p.m. and 7:00 a.m. |
| Ambient Noise Level | The composite of noise from all sources near and far. The normal or existing level of environmental noise at a given location. |
| Intrusive | That noise which intrudes over and above the existing ambient noise at a given location. The relative intrusiveness of a sound depends upon its amplitude, duration, frequency, and time of occurrence and tonal or informational content as well as the prevailing ambient noise level. |

**TABLE 2 Typical Noise Levels in the Environment**

| Common Outdoor Activities | Noise Level (dBA) | Common Indoor Activities |
|---|---|---|
| | 110 dBA | Rock band |
| Jet fly-over at 1,000 feet | | |
| | 100 dBA | |
| Gas lawn mower at 3 feet | | |
| | 90 dBA | |
| Diesel truck at 50 feet at 50 mph | | Food blender at 3 feet |
| | 80 dBA | Garbage disposal at 3 feet |
| Noisy urban area, daytime | | |
| Gas lawn mower, 100 feet | 70 dBA | Vacuum cleaner at 10 feet |
| Commercial area | | Normal speech at 3 feet |
| Heavy traffic at 300 feet | 60 dBA | |
| | | Large business office |
| Quiet urban daytime | 50 dBA | Dishwasher in next room |
| Quiet urban nighttime | 40 dBA | Theater, large conference room |
| Quiet suburban nighttime | | |
| | 30 dBA | Library |
| Quiet rural nighttime | | Bedroom at night, concert hall (background) |
| | 20 dBA | |
| | | Broadcast/recording studio |
| | 10 dBA | |
| | 0 dBA | |

**TABLE 3-A Guideline Vibration Damage Potential Threshold Criteria**

| Structure and Condition | Maximum PPV (in/sec) | |
|---|---|---|
| | Transient Sources | Continuous/Frequent Intermittent Sources |
| Extremely fragile historic buildings, ruins, ancient monuments | 0.12 | 0.08 |
| Fragile buildings | 0.2 | 0.1* |
| Historic and some old buildings | 0.5 | 0.25 |
| Older residential structures | 0.5 | 0.3 |
| New residential structures | 1.0 | 0.5 |
| Modern industrial/commercial buildings | 2.0 | 0.5 |
| Note: Transient sources create a single isolated vibration event, such as blasting or drop balls. Continuous/frequent intermittent sources include impact pile drivers, pogo-stick compactors, crack-and-seat equipment, vibratory pile drivers, and vibratory compaction equipment. | | |
| * For damage to historic buildings, 0.12 PPV is used from Wilson, Ihrig & Associates et al., 2012 as discussed in Section 4.6.<br>Source: Transportation and Construction Vibration Guidance Manual, California Department of Transportation, September 2013. | | |

**TABLE 3-B Guideline Vibration Annoyance Potential Criteria**

| Human Response | Maximum PPV (in/sec) | |
|---|---|---|
| | Transient Sources | Continuous/Frequent Intermittent Sources |
| Barely perceptible | 0.035 | 0.01 |
| Distinctly perceptible | 0.24 | 0.04 |
| Strongly perceptible | 0.9 | 0.10 |
| Severe | 2.0 | 0.4 |
| Note: Transient sources create a single isolated vibration event, such as blasting or drop balls. Continuous/frequent intermittent sources include impact pile drivers, pogo-stick compactors, crack-and-seat equipment, vibratory pile drivers, and vibratory compaction equipment. | | |

## Regulatory Background

Federal, State, and local governments and agencies regulate noise in the environment and industry. There are no federal or state laws or regulations that would apply to the noise resulting from the construction or operation of the GWR project. The California Environmental Quality Act (CEQA) outlines the questions that form the basis of the significance criteria presented later in this report. Applicable regulatory criteria established by the County of Monterey, City of Salinas, City of Marina, City of Seaside, and City of Monterey are as follows:

### *County of Monterey*

Monterey County's exterior noise exposure standards are based on parameters established by the California Department of Health, Office of Noise Control and are presented in Table 4. Based on these standards, noise levels of 60 dBA $L_{dn}$ or less at various noise-sensitive receptor locations, including single- and multi-family residences, schools, hospitals, churches, and nursing homes are considered "normally acceptable" and noise levels of 60 to 70 dBA $L_{dn}$ are considered "conditionally acceptable" with the incorporation of noise insulation and mitigation features (Monterey County, 1993).

> *Policy S-7.2:* Proposed development shall incorporate design elements necessary to minimize noise impacts on surrounding land uses and to reduce noise in indoor spaces to an acceptable level.
>
> *Policy S-7.4:* New noise generators may be allowed in areas where projected noise levels are "conditionally acceptable" only after a detailed analysis of the noise reduction requirements is made and needed noise mitigation features are included in project design.
>
> *Policy S-7.5:* New noise generators should generally be discouraged in areas identified as "normally unacceptable." Where such new noise generators are permitted, mitigation to reduce both the indoor and outdoor noise levels will be required.
>
> *Policy S-7.6:* Acoustical analysis shall be part of the environmental review process for projects when:
>
> a. Noise sensitive receptors are proposed in areas exposed to existing or projected noise levels that are "normally unacceptable" or higher according to Table S-2 (presented as Table 4).
>
> b. Proposed noise generators are likely to produce noise levels exceeding the levels shown in the adopted Community Noise Ordinance when received at existing or planned noise-sensitive receptors.
>
> *Policy S-7.8:* All discretionary projects which propose to use heavy construction equipment that has the potential to create vibrations that could cause structural damage to adjacent structures within 100 feet would be required to submit a pre-construction vibration study prior to the approval of a building permit. Specified measures and monitoring identified to reduce impacts would be incorporated into construction contracts. Pile driving or blasting are illustrative of the type of equipment that could be subject to this policy.
>
> *Policy S-7.9:* No construction activities pursuant to a County permit that exceed levels listed in Policy S-7.1 (herein Table 4) shall be allowed within 500 feet of a noise sensitive land use during the evening hours of Monday through Saturday, or anytime on Sunday or holidays shall be allowed prior to completion of a noise mitigation study. Noise protection measures, in the event of any identified impact, may include but not be limited to:
>
> - Constructing temporary barriers; or
> - Using quieter equipment than normal.
>
> *Policy S-7.10:* Standard noise protection measures shall be incorporated into all construction contracts. These measures shall include:

- Construction shall occur only during times allowed by ordinance/code unless such limits are waived for public convenience;
- All equipment shall have properly operating mufflers; and
- Lay-down yards and semi-stationary equipment such as pumps or generators shall be located as far from noise-sensitive land uses as practical.

In addition, the Monterey County Noise Control Ordinance (Chapter 10.60 of the County Code) prohibits the operation of any device, which produces a noise level exceeding 85 dBA at a distance of 50 feet from the source, but does not apply to aircraft or any machine or device that is operated in excess of 2,500 feet from any occupied dwelling unit. Additionally, section 10.60.040 of the County Code apply to nighttime noise, in which it is prohibited to make, assist in making, allow, continue, create, or cause to be made any loud and unreasonable sound any day of the week from 10:00 p.m. to 7:00 a.m. the following morning within the unincorporated area of the County of Monterey. During this time period, a loud and unreasonable sound includes any sound that exceeds the exterior noise level standards set forth below:

| | |
|---|---|
| Nighttime hourly equivalent sound level ($L_{eq}$ dBA) | 45 |
| Maximum level, dBA | 65 |

Noise levels shall be measured at or outside the property line of the property from which noise is emanating. Commercial agricultural operations, emergency vehicles, bells and chimes used for religious purposes or services, and specified outdoor gatherings are exempt from these requirements.

***City of Salinas***

**Noise Element of the City of Salinas General Plan**

The Noise Element of the Salinas General Plan sets forth goals and policies to protect citizens from the harmful and annoying effects of excessive noise. Policies established in the Noise Element of the General Plan that are applicable to the proposed project include:

**Goal N-1: Minimize the adverse effects of noise through proper land use planning.**

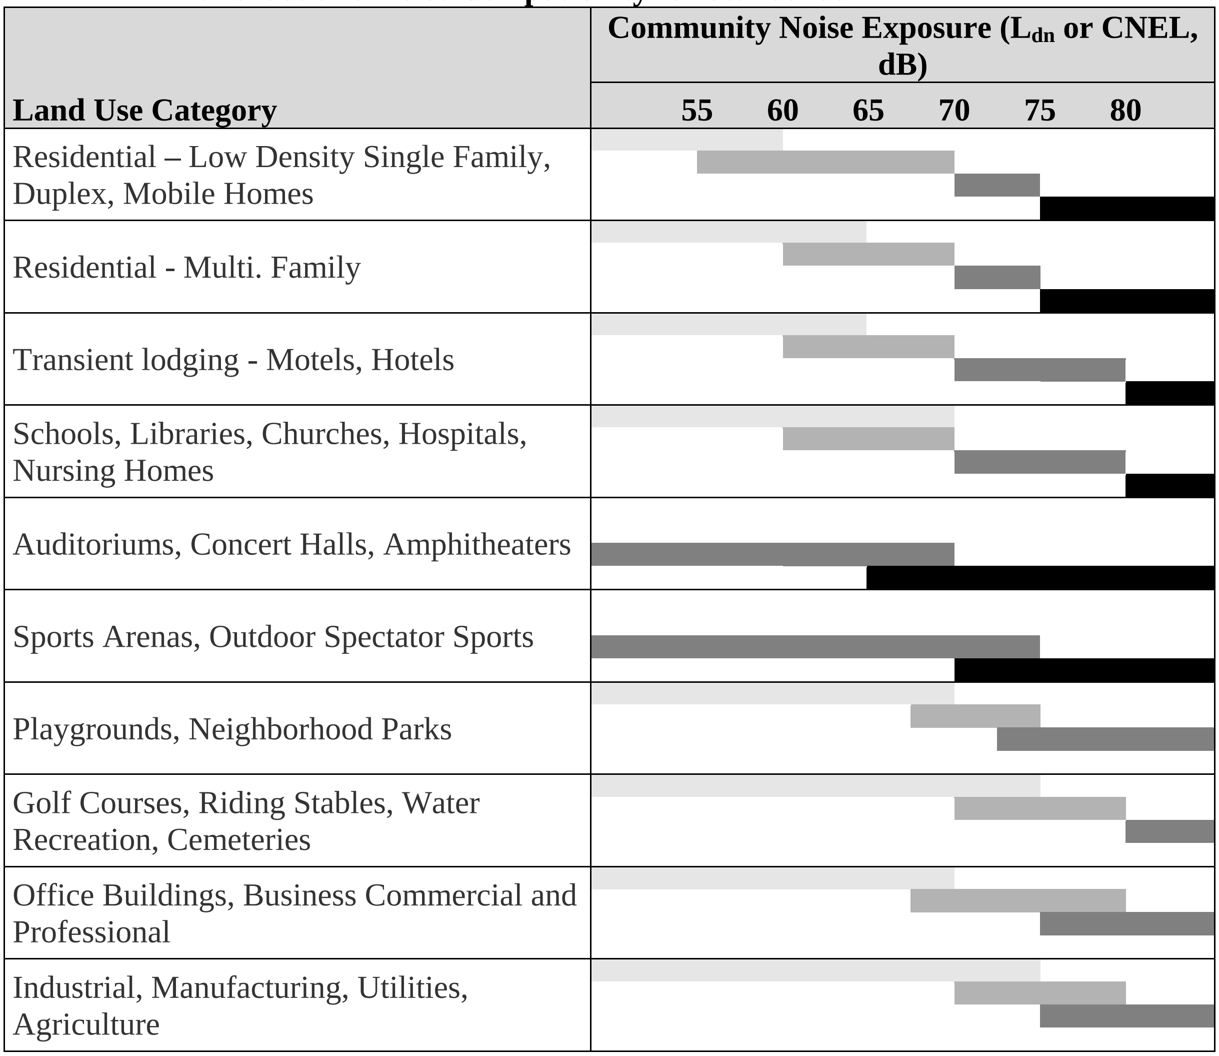
*Policy N-1.1:* Ensure that new development can be made compatible with the noise environment by using noise/land use compatibility standards Table N-3 (herein Table 5) and the Noise Contours Map (not included) as a guide for future planning and development decisions.

The following goal and policies address the noise created by non-transportation related sources.

**Goal N-3: Minimize non-transportation related noise impacts.**

*Policy N-3.1:* Enforce the City of Salinas Noise Ordinance to ensure stationary noise sources and noise emanating from construction activities, private developments/residences, and special events are minimized. The exterior noise standards are shown in Table 6.

**TABLE 4 Land Use and Noise Compatibility for Standards**



Source: County of Monterey, 2007.

***INTERPRETATION***

NORMALLY ACCEPTABLE: Specified land use is satisfactory, based upon the assumption that any buildings involved are of normal conventional construction, without any special noise insulation requirements.

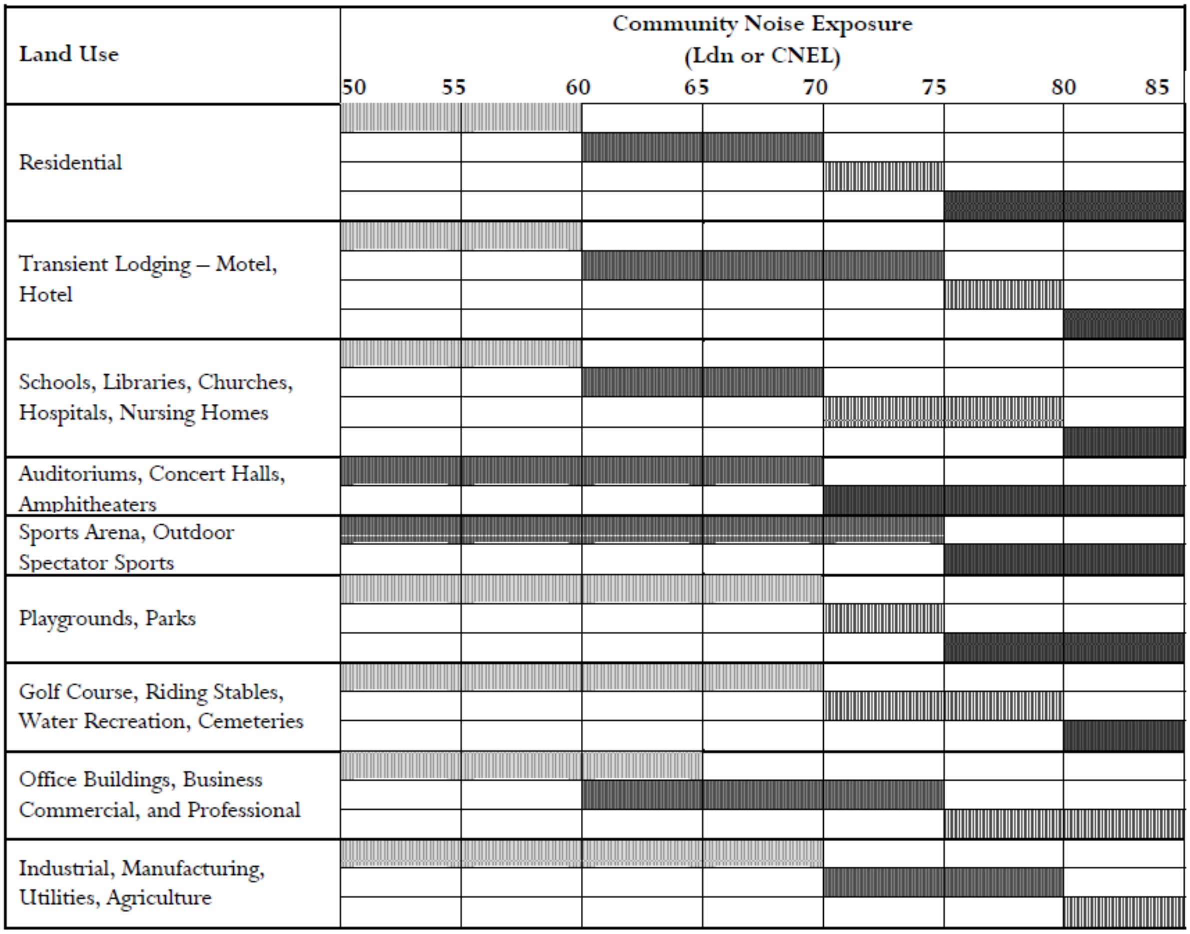
CONDITIONALLY ACCEPTABLE: New construction or development should be undertaken only after a detailed analysis of noise reduction requirements is made and needed noise insulation features included in the design. Conventional construction, but with closed windows and fresh air supply systems or air conditioning will normally suffice.

NORMALLY UNACCEPTABLE: New construction or development should generally be discouraged. If new development or construction does proceed, a detailed analysis of the noise reduction requirements must be made and needed noise insulation features included in the design.

CLEARLY UNACCEPTABLE: New construction or development should generally not be undertaken.

## TABLE 5   City of Salinas General Plan Noise/Land Use Compatibility Matrix

**Table N-3**
**Noise/Land Use Compatibility Matrix**



Source: Modified by CBA from 1998 State of California General Plan Guidelines.

**ZONE A - Normally Acceptable:** Specified land use is satisfactory, based upon the assumption that any buildings involved meet conventional Title 24 construction standards. No special noise insulation requirements.

**ZONE B - Conditionally Acceptable:** New construction or development shall be undertaken only after a detailed noise analysis is made and noise reduction measures are identified and included in the project design.

**Zone C- Normally Unacceptable:** New construction or development is discouraged. If new construction is proposed, a detailed analysis is required, noise reduction measures must be identified, and noise insulation features included in the design.

**ZONE D- Clearly Unacceptable:** New construction or development clearly should not be undertaken.

**TABLE 6 City of Salinas General Plan Exterior Noise Standards**

| Designation/District of Property Receiving Noise | Maximum Noise Level, $L_{dn}$ or CNEL, dBA |
|---|---|
| Agricultural | 70 |
| Residential | 60 |
| Commercial | 65 |
| Industrial | 70 |
| Public and Semipublic | 60 |

**City of Salinas Zoning Ordinance**

Pursuant to section 37.50-180 of the Salinas Municipal Code, the following performance standards shall apply to all use classifications in all zoning districts:

> **(a) Noise:** No use shall create ambient noise levels which exceed the following standards (see Table 37-50.50, herein Table 7), as measured at the property boundary:
>
> *(1)Duration and Timing.* The noise standards in Table 37-50.50 shall be modified as follows to account for the effects of time and duration on the impact of noise levels:
>
> (A) In residential zones, the noise standard shall be 5.0 dBA lower between 9:00 p.m. and 7:00 a.m.
>
> (B) Noise that is produced for no more than a cumulative period of five minutes in any hour may exceed the standards above by 5.0 dBA.
>
> (C) Noise that is produced for no more than a cumulative period of one minute in any hour may exceed the standards above by 10.0 dBA.
>
> Note: The interior noise level in any residential dwelling unit located in a mixed use building or development shall not exceed a maximum of forty-five dBA from exterior ambient noise.

The city planner may require an acoustic study for any proposed project or use that has the potential to create a noise exposure greater than that deemed acceptable by the above standard, and require appropriate mitigation measures.

Chapter 21A of the Salinas Municipal Code prohibits unnecessary, excessive and annoying noise from specified noise sources, but does not specifically address construction noise.

**TABLE 7 City of Salinas Zoning Ordinance Noise Standards**

| Table 37-50.50 Maximum Noise Standards | |
|---|---|
| **Zone of Property Receiving Noise** | **Maximum Noise Level (CNEL, dBA)** |
| Agricultural District | 70 dBA |
| Residential Districts | 60 dBA |
| Commercial Districts | 65 dBA |
| Industrial Districts | 70 dBA |
| Mixed Use Districts | 65 dBA(A) |
| Parks/Open Space Districts | 70 dBA |
| Public/Semipublic District | 60 dBA |

***City of Marina***

**General Plan and Municipal Code**

The General Plan (Table 4.1) establishes the maximum allowable exterior and interior noise levels for different land use categories. The noise standards apply to the siting of new noise-sensitive receptors (in particular residences, schools, and parks), and the siting of new or improved arterials and collectors near noise-sensitive receptors. The General Plan of the City of Marina (Table 4.2) features noise standards for new or modified stationary noise sources that adjoin or are in close proximity to residential or other noise-sensitive uses (see Table 8).

**TABLE 8 City of Marina Noise Standards for Stationary Noise Sources**

| **Duration** | **Maximum Allowable Noise** | |
|---|---|---|
| | Day (7:00 a.m. to 10:00 p.m.) | Night (10:00 p.m. to 7:00 a.m.) |
| Hourly $L_{eq}$ in dB [1,2] | 50 | 45 |
| Maximum Level in dB [1,2] | 70 | 65 |
| Maximum Impulsive Noise in dB [1,3] | 65 | 60 |

[1]*As determined at the property line of the receptor. When determining the effectiveness of noise mitigation measures, the standards may be applied on the receptor side of noise barriers or other property-line noise mitigation measures.*
[2]*Sound level measurements shall be made with slow meter response.*
[3]*Sound level measurements shall be made with fast meter response.*

The City of Marina Municipal Code (Chapter 9.24) establishes noise regulations within Marina. Pursuant to section 9.24.040.D, operation or use of a range of tools and power equipment is limited to between the hours of 7 a.m. and 7 p.m. on Monday through Saturday, 10 a.m. and 7 p.m. on Sundays and holidays, and until 8 p.m. when daylight savings time is in effect. Excessive, unnecessary or unusually loud noise due to construction, demolition, and excavation that disturbs occupants of residential property also is considered in violation of the City's noise regulations pursuant to section 9.24.040E. However, section 9.24.050 exempts activities on or in publicly owned property and facilities, or by public employees or city franchisees, while in the authorized discharge of their responsibilities, provided that such activities have been authorized by the owner of such property or facilities or its agent.

Title 15 of the Marina Municipal Code (Buildings and Construction) also addresses construction noise. Section 15.04.055 prohibits any outside construction, repair work or related activities requiring a building, grading, demolition, use or other permit from the city when construction noise is produced adjacent to residential uses, including transient lodging, except between the hours of 7 a.m. and 7 p.m. (standard time), and on Sundays and holidays between the hours of 10 a.m. and 7 p.m. (standard time). During daylight savings time, the hours of construction may be extended to 8 p.m. This section of the Municipal code further indicates that during hours of construction, no construction, tools or equipment shall produce a noise level of more than 60 decibels for twenty-five percent of an hour during construction at any receiving property line.

***City of Seaside***

The City of Seaside provides goals and policies and plans regarding Noise and Land Use Planning and construction noise, as shown below:

**Policy N-1.1**: Ensure that new development and reuse/revitalization projects can be made compatible with the noise environment and existing development.

**Implementation Plan N-1.1.1: Compatible Development**

Review discretionary development proposals for potential on- and off-site stationary and vehicular noise impacts per CEQA. Any proposed development located within a 60 dB or higher noise contour shall be reviewed for potential noise impacts and compliance with the noise and land use compatibility standards. The thresholds established in the Zoning Ordinance, Noise Ordinance, the Noise Contours Map (not included here), and the Tables N-1 and N-2 (herein Tables 9 and 10) of the Noise Element will be used to determine the significance of impacts.

If potential impacts are identified, mitigation in the form of noise reduction designs/structures will be required to reduce the impact to a level less than significant. If the impact cannot be reduce to a level less than significant or avoided with accepted noise reduction methods, the proposed project will be determined “Clearly Unacceptable” and will not be approved.

**TABLE 9 City of Seaside Maximum Exterior and Interior Noise Standards**

| | **Noise Standard in CNEL** | |
|---|---|---|
| **Land Use** | Exterior (dBA) | Interior (dBA) |
| Residential | 65 | 45 |
| Mixed Use Residential | 70 | 45 |
| Commercial | 70 | --- |
| Office | 70 | 50 |
| Industrial | 75 | 55 |
| Public Facilities | 70 | 50 |
| Schools | 80 | 50 |

Source: City of Seaside, 2008.

**Implementation Plan N-3.1.3 Construction Noise Limits**

Require all construction activity to comply with the limits (maximum noise levels, hours, and days allowed activity) established in the City noise regulations (Title 24 California Code of Regulations, Zoning Ordinance and Chapter 21A of the Municipal Code).

**TABLE 10 City of Seaside Land Use Compatibility Guidelines**

| | Community Noise Equivalent Level (CNEL) | | | | | |
|---|---|---|---|---|---|---|
| **Land Use Category** | **55** | **60** | **65** | **70** | **75** | **80** |
| Residential – Single-Family, Multi-Family, and Duplex | A | B | B | C | - | - |
| Residential – Mobile homes | A | B | C | C | - | - |
| Transient Lodging - Hotels and Motels | A | B | B | C | C | |
| Hospitals, Libraries, Nursing Homes, Places of Worship, and Schools | A | B | C | C | - | - |
| Amphitheaters, Auditoriums, Concert Halls, and Meeting Halls | B | C | C | - | - | - |
| Amusement Parks, Outdoor Spectator Sports, and Sports Arenas | A | A | B | B | - | - |
| Neighborhood Parks and Playgrounds | A | A | B | C | - | - |
| Cemeteries, Golf Courses, and Riding Stables | A | A | A | B | C | C |
| Office and Professional Buildings | A | A | B | B | C | - |
| Banks, Commercial Retail, Restaurants, and Theaters | A | A | A | B | B | C |
| Industrial, Manufacturing, Service Stations, Utilities, and Wholesale | A | A | A | B | B | B |
| Agriculture | A | A | A | A | A | A |

Notes:
A = Normally Acceptable. Specified land use is satisfactory based on the assumption that any structures involved are normal conventional construction, without any special noise insulation requirements.
B = Conditionally Acceptable. New construction or development may be undertaken only after a detailed analysis of the noise requirements is made and needed noise insulation features as included in the design. Conventional construction, but with closed windows and fresh air supply systems or air conditioning will normally suffice.
C = Normally Unacceptable. New construction or development shall generally be discouraged. If it does proceed, a detailed analysis of the noise reduction requirements shall be made and needed noise insulation features included in the design.
- = Clearly Unacceptable. New construction or development shall generally not be undertaken.

Source: City of Seaside, 2004 and 2008.

Chapter 9.12 of the City of Seaside Municipal Code establishes noise regulations within Seaside. Pursuant to section 9.12.030.D, operation or use of a range of tools and power equipment and any construction, demolition, excavation, erection, alteration, or repair activity is declared to be unlawful and a nuisance if it occurs before 7:00 a.m. or after 7:00 p.m. daily (except Saturday, Sunday, and holidays when the prohibited time shall be before 9:00 a.m. and after 7:00 p.m.)

unless authorized in writing by a building official. Written authorization may be issued in the case of an emergency, or where the building official determines that the peace, comfort and tranquility of the occupants of residential property will not be impaired because of the location or nature of the construction activity. Section 9.12.040.D exempts activity on or in publicly owned property and facilities, or by public employees or their franchisees, while in the authorized discharge of their responsibilities, provided such activities have been authorized by the owner of such property or facilities or its agency or by the employing authority.

Seaside's Municipal Code Section 17.30.060 of Title 17 (Zoning Ordinance) establishes noise standards to implement policies of the Noise Element of the General Plan and to protect the community health, safety and general welfare by limiting exposure to the unhealthful effects of noise. No "use, activity, or process shall exceed the maximum allowable noise levels" established in this section, except for "construction, maintenance, and/or repair operations by public agencies and/or utility companies or their contractors that are serving public interest and/or protecting the public health, safety, and general welfare" (section 17.30.060B.3). The maximum noise standards are included in this section as shown on Table 9. The section also indicates that Chapter 9.12 regulates the noise generated from all uses, activities and processes conducted within the City.

***City of Monterey***

The City of Monterey General Plan identifies the following goals for new development related to noise that may be applicable to the project (City of Monterey, 2005):

> **Goal d:** Allow new construction only where existing or projected noise levels are acceptable or can be mitigated.
>
> *Policy d.2:* Limit hours of noise generating construction activities. Include this requirement

City of Monterey Municipal Code Section 38-111 (A) identifies performance standards to be applied to all use classification in all zoning districts. Decibel levels are required to be compatible with neighboring uses, and no use shall create ambient noise levels which exceed the standards identified in Table 11. It should be noted that the Community Development Director may require an acoustic study for any proposed project that could have, or create, a noise exposure greater than that identified in the table.

**TABLE 11 CITY OF MONTEREY MAXIMUM NOISE STANDARDS**

| Zone of Property Receiving Noise | Maximum Noise Level (dBA) |
|---|---|
| OS - Open Space District | 60 |
| R - Residential Districts | 60 |
| PS - Public and Semi-Public District | 60 |
| C - Commercial District | 65 |
| I - Industrial Districts | 70 |
| PD - Planned Development | Study Required |
| Notes: These noise standards shall be modified as follows to account for the effects of time and duration on the impact of noise levels: In R districts, the noise standard shall be 5 dB lower between 10:00 p.m. and 7:00 a.m.; noise that is produced for no more than a cumulative period of five minutes in any hour may exceed the standards above by 5 dB; and noise that is produced for no more than a cumulative period of one minute in any hour may exceed the standards above by 10 dB. | |

Source: City of Monterey Municipal Code Section 38-111

Section 38-112.2 of the City's Municipal Code limits the hours of construction for activities authorized by a building permit to the following: Monday through Friday between the hours of 7:00 a.m. and 7:00 p.m., on Saturday between 8:00 a.m. and 6:00 p.m., and on Sunday between 10:00 a.m. and 5:00 p.m. Pursuant to this section, a permit may be issued by the Zoning Administrator for requests to conduct construction activity outside listed hours for unique circumstances.

**Existing Noise Environment**

The project will take place at several sites within northern Monterey County, California. A noise monitoring survey was performed between December 20, 2013 and December 27, 2013 to establish existing baseline noise levels at representative noise sensitive receptors located near project components. Some land uses are considered more sensitive to ambient noise levels than others. In general, residences, schools, hotels, hospitals, and nursing homes are considered to be the most sensitive to noise. Places such as churches, libraries, and cemeteries, where people tend to pray, study, and/or contemplate are also sensitive to noise. Commercial and industrial uses including agricultural lands are considered the least noise-sensitive.

*Sensitive Receptors*

The following paragraphs provide summary descriptions of the sensitive receptor locations in the vicinity of the several project sites.

<u>Regional Treatment Plant</u>: New facilities at the Regional Treatment Plant (RTP) would include pre-treatment, an Advanced Water Treatment (AWT) Facility, and concentrate disposal facilities. The nearest sensitive receptors are a farm house off Monte Road in Monterey County located about one mile to the northwest of the AWTP site, and residences along Cosky Drive in Marina located at a distance of about 5,400 feet to the southwest of the AWTP site.

Salinas Pump Station: New facilities at the Salinas Pump Station would include diversion structures and short pipelines to re-direct urban runoff and storm water, and agricultural wash water to the RTP for advanced water treatment. The nearest sensitive receptors are several farmhouses located in Monterey County, one about 1,400 feet north of the pump station along Blanco Road, one about 1,500 feet west of the pump station along S. Davis Road, and several residences located about 1,700 to 2,000 feet south of the pump station along Hitchcock Road. Residences in Salinas are located about 2,200 feet east of the pump station along Las Cruces Court and Las Cruces Way.

Salinas Industrial Wastewater Treatment Facility (Salinas Treatment Facility) Storage and Recovery: The proposed project would be located along the Salinas River south of Blanco Road and west of Davis Road, and includes improvements that would enable the agricultural wash water to be conveyed from the ponds at the Salinas Industrial Wastewater Treatment Facility to the Regional Treatment Plant for recycling. Components of the project include a wet well/diversion structure, flow meter, valves, and on-site surge tank, connecting pipelines, electrical cabinet, concrete lining of channel banks, and pipelines. The nearest sensitive receptors are residences located more than 2,500 feet southeast of the project site, across Davis Road

Reclamation Ditch Diversion Site: New facilities at the Reclamation Ditch Diversion site near Davis Road would include the diversion of surface water to a nearby manhole. Project components include a pump, electrical cabinet, flow meter and valves, and short connecting pipelines. The nearest sensitive receptors are residences located about 1,000 feet west of the new equipment. The site lies along the western border of Salinas, upstream of the Tembladero Slough.

Tembladero Slough Diversion: Improvements to divert water to the Regional Treatment Plant at the Tembladero Slough site would include the diversion of surface waters to an existing wet well. Project components include an electrical pump/cabinet, flow meter and valves, and short connecting pipelines. The nearest sensitive receptors are residences located about 750 feet north of the new equipment. Another residence is located across Highway 1, 850 feet east of the new equipment. The site lies west of Highway 1 near Watsonville Road, downstream of the Reclamation Ditch Diversion.

Blanco Drain Diversion Site: Proposed changes at the Blanco Drain Agricultural Land Runoff would include the diversion of surface waters from agricultural tile drains with a new pump station at the site. Project components include a diversion structure, flow meter and valves, an on-site surge tank, electrical cabinet, concrete lining, and approximately 8,500 LF of force main gravity pipeline from the site to the Regional Treatment Plant (SVRP modifications). The nearest sensitive receptor is a residence located more than 2,400 feet northeast of the new pump station. Additionally, a residence is located about 3,000 feet southeast of the proposed pipeline and a residential neighborhood is located more than a mile to the southwest of the pipeline and SVRP modifications. The site lies along the Salinas River, east of the Monterey Regional Waste Management District facility.

Lake El Estero Diversion Site: New facilities at El Estero would include either a column pump or a gravity system and motorized valve, and short connecting pipelines. The improvements would be in the existing structure or underground. The nearest sensitive receptor is the Monterey Bay Lodge located about 350 feet east-southeast of the facility and the nearest residential receptor is located about 500 feet southeast of the facility in the City of Monterey. The site lies within the El Estero recreation area.

New Booster Pump Station Sites: The proposed new Booster Pump Station would receive flow from the Product Water Conveyance Pipeline and pump the product water into one of the two proposed alternative alignments that merge to a single alignment along General Jim Moore Boulevard. Because of noise considerations, the pump motors and discharge piping would be housed in a split-faced block, or similar building with appropriate architectural treatments. There are two options for the site of the Booster Pump Station site depending upon the selected product water pipeline route, with RUWAP Option located along the Regional Urban Water Augmentation Project (RUWAP) alignment and Coastal Option along the Coastal alignment. The RUWAP Option is located in the City of Marina Corp Yard parking lot off 5th Avenue in Marina about 90 feet south of the building. The nearest sensitive receptors are the residents of the California State University Monterey Bay (CSUMB) campus housing located about 650 feet to the west of the Booster Pump Station site and the CSUMB classroom building located about 450 feet southwest of the site. The Coastal Option is located on CSUMB property at the southwest corner of the intersection of 2nd Avenue and Divarty Street. There are no residential receptors in the vicinity of the site. Abandoned buildings are located to the north across Divarty Street from the site. Vacant land is located to the west and south of the site. CSUMB recreation facilities are located to the east across 2nd Avenue. The nearest recreation facilities include a swimming pool located about 750 feet east of the Booster Pump Station site and a child development center located about 875 feet northeast of the site.

Project Water Pipeline Routes: The Proposed Project would include construction of a pipeline to convey the advanced treated product water from the proposed AWT Facility to the Seaside Groundwater Basin for injection, along one of two potential pipeline alignments. One option would generally follow the RUWAP recycled water pipeline route through the City of Marina, CSUMB, and the City of Seaside. The other option, referred to herein as the Coastal Alignment, would follow in parallel with a portion of the proposed new CalAm Monterey Peninsula Water Supply Project desalination product water pipeline along the eastern side of the Transportation Agency of Monterey County (Transportation Agency) railroad tracks. The southern portion of the Coastal Alignment would also be located in the former Fort Ord within CSUMB and the City of Seaside.

The RUWAP alignment would pass through open land and then follow Crescent Avenue south for about 4,000 feet, and then through several other local streets, including California Avenue and 5th Avenue, until eventually intersecting General Jim Moore Boulevard. The pipeline route would be along the eastern side of the right of way of General Jim Moore Boulevard approximately 2 miles, past the developed military housing area (called Fitch Park), through the open land around a water reservoir used by the nearby golf courses, connecting to Eucalyptus Road, then southerly to the Injection Well Facilities area (this portion of the conveyance system applies to both the Coastal and RUWAP Alignments). The Crescent Avenue to California Drive segment is in residential streets within the City of Marina until the intersection with Patton Parkway. South of Patton Parkway and South of the Booster Pump Station the alignment enters the City of Seaside and passes by CSUMB residential, classroom, student center, and dining facilities before continuing south down General Jim Moore Boulevard where sensitive receptors include residences, a church, recreation facilities, and mixed commercial/residential areas.

The Coastal Alignment would be located between 50 to 100 feet east of residences along Del Monte Boulevard and Marina Drive from Marina Green Drive where it enters developed area in Marina to Palm Avenue. South of Palm Avenue, the pipeline would be approximately 100 feet east of play fields associated with the Marina Del Mar Elementary School and would be approximately 350 feet east of the nearest building associated with this elementary school. The Coastal Alignment would continue south, under the Highway 1 overpass, past MRWPCA's Fort Ord Pump Station to Divarty Street. From this point, the Coastal Alignment would cease to parallel the proposed CalAm Monterey Peninsula Water Supply Project pipeline alignment. The GWR Coastal Alignment would cross under Highway One at the Divarty Street underpass. The pipeline would follow Divarty Street to Second Avenue, where the Booster Pump Station would be located. Land uses along 2nd Avenue include unoccupied buildings and open land. From the proposed Booster Pump Station site, the pipeline would turn south and follow on the west side of Second Avenue to Lightfighter Drive. At the intersection of Second Avenue and Lightfighter Drive the pipeline would be constructed under Lightfighter Drive by either directional drilling or bore and jack techniques to avoid disruption to this main thoroughfare. From this intersection the alignment would turn eastward and would be constructed on the south side of the Lightfighter Drive roadway, but off the pavement, up to the intersection with General Jim Moore Boulevard. The pipeline would follow the southbound ramp from Lightfighter Drive onto General Jim Moore Boulevard where it would merge to the same alignment as the RUWAP alignment. There are no sensitive receptors in the vicinity of the Coastal Alignment south of the Booster Pump Station site until it joins the RUWAP alignment.

<u>Injection Wells/Back-flush Facilities Site:</u> The proposed new Injection Well Facilities would be located east of General Jim Moore Boulevard, south of Eucalyptus Road in the City of Seaside, including a total of eight wells (four deep injection wells, four vadose zone wells), monitoring wells, and backflush facilities, at an area formerly referred to as the Inland Recharge Area. Each injection well would be equipped with a well pump to back-flush the well. Injection wells would require a permanent power supply to the site, including electrical equipment, two electrical control buildings for back-flush pumps, external electrical control cabinets at the well clusters, wiring and connections of electrical power, and instrumentation and control facilities. Other than the wellheads, small electric control cabinets would be the only above ground electrical components at the injection wells. The nearest sensitive receptors are residences located west of General Jim Moore Boulevard at distances of 500 to 700 feet from the nearest proposed well sites and about 1,200 feet from the proposed back-flush facility.

*Noise Survey*

The noise survey consisted of four unattended long-term noise measurements and two attended short-term noise measurements. Noise levels were monitored using Larson-Davis Laboratories Model 820 integrating sound level meters fitted with precision microphones and windscreens. The meters were calibrated before and after the measurements. Long-term (LT) reference noise measurements were made to quantify the daily trend in noise levels and to establish the existing day-night average noise level. Long-term noise measurement locations were selected to generally represent reference noise levels from a primary noise source or human activity areas along the project corridor. Care was taken to avoid those sites where extraneous noise sources such as barking dogs, pool pumps, or air conditioning units could contaminate the noise data. Short-term (ST) noise measurements were also made along the project corridor in concurrent time intervals with the data collected at the long-term reference measurement sites. This method facilitates a direct comparison between both the short-term and long-term noise measurements and allows for the identification of the day-night average noise level at land uses in the project vicinity where long-term noise measurements were not made. At all short-term locations, noise levels were measured five feet above the ground surface and at least 10 feet from structures or barriers. Weather conditions during the survey included gentle winds and mild temperatures. Long-term measurement data are shown in Appendix A.

Long-term noise measurement LT-1 was 65 feet west of the center of General Jim Moore Boulevard and approximately 380 feet south of Coe Avenue in Seaside, California. The measurement was located near residential property lines (backyards) along General Jim Moore Boulevard at a height of twelve feet above the ground. Hourly average noise levels typically ranged from 57 to 66 dBA $L_{eq}$ during the day, and from 47 to 56 dBA $L_{eq}$ at night. Calculated day-night average noise levels at this location ranged from 61 to 63 dBA $L_{dn}$ over six 24-hour periods.

Long-term noise measurement LT-2 was 200 feet north of the center of Del Monte Avenue along the Monterey Peninsula Recreational Trail in Monterey, California. The measurement was located amid a park just south of Municipal Beach at a height of twelve feet above the ground. Hourly average noise levels typically ranged from 56 to 66 dBA $L_{eq}$ during the day, and from 53 to 61 dBA $L_{eq}$ at night. Calculated day-night average noise levels at this location ranged from 63 to 66 dBA $L_{dn}$ over eight 24-hour periods.

Noise measurement LT-3 was 20 feet west of the center of Vaughan Avenue, north of Reindollar Avenue in Marina, California. The measurement was located in a neighborhood of single-family residential houses at a height of twelve feet above the ground. Hourly average noise levels typically ranged from 54 to 66 dBA $L_{eq}$ during the day, and from 43 to 56 dBA $L_{eq}$ at night. Calculated day-night average noise levels at this location ranged from 56 to 61 dBA $L_{dn}$ over seven 24-hour periods. The lower day-night average levels (56 dBA $L_{dn}$ and 58 dBA $L_{dn}$) were measured and calculated during Christmas day.

Noise measurement LT-4 was located at the dead-end of Las Cruces Way, at the border of an agricultural land use and a neighborhood of single-family residences in Salinas, California. The measurement was at a height of twelve feet above the ground. Hourly average noise levels typically ranged from 45 to 74 dBA $L_{eq}$ during the day, and from 38 to 50 dBA $L_{eq}$ at night. Calculated day-night average noise levels at this location ranged from 55 to 65 dBA $L_{dn}$ over six 24-hour periods. Again, the lowest day-night average level was measured during Christmas day.

Two attended short-term noise measurements (ST-1 & ST-2) completed the noise monitoring survey. These measurements were made after a.m. peak traffic hours. Noise measurement ST-1 was made to represent proposed project construction noise during drilling activity at an injection well site and was located approximately 50 feet from a running truck engine and 75 feet from the operating drill rig. The drill rig and truck engine were dominant noise sources during the measurement and resulted in average noise levels of 83 dBA $L_{eq}$ during drilling and 81 dBA $L_{eq}$ while backing out the drill. ST-1 was located more than 1,000 feet east of General Jim Moore Boulevard, along Eucalyptus Road, which was closed to through traffic due to construction. Noise measurement ST-2 was located along Juarez Street, 315 feet west of the center of General Jim Moore Boulevard. This location is representative of residences in the area at the nearest set-back from General Jim Moore Boulevard, which was the dominant noise during the measurement, resulting in average noise levels of 47 and 48 dBA $L_{eq}$. Table 12 summarizes the results of these short-term measurements.

**TABLE 12 - Summary of Short-Term Noise Measurements (dBA)**

| Noise Measurement Location | Date Time | $L_{eq}$ | $L_{max}$ | $L_{(10)}$ | $L_{(50)}$ | $L_{(90)}$ | $L_{dn}$* |
|---|---|---|---|---|---|---|---|
| ST-1: Water pipe drilling site in Seaside. 75 feet from drill rig, 50 feet from truck engine. | 12/19/2013 9:40-10:00 a.m. | 83 | 89 | 84 | 83 | 82 | 89 |
| | 10:00-10:10 a.m. | 81 | 84 | 83 | 82 | 67 | |
| ST-2: South of Seaside pump station along Juarez Street, 315 feet from the center of General Jim Moore Blvd. | 12/27/2013 11:00-11:10 a.m. | 48 | 60 | 49 | 46 | 44 | 49 |
| | 11:10-11:20 a.m. | 47 | 55 | 48 | 46 | 45 | 48 |

* $L_{dn}$ levels at ST-1 assume continuous 24-hour operations of the drilling operation. $L_{dn}$ levels at ST-2 were estimated based on noise levels measured at LT-1 during corresponding interval.

## NOISE IMPACTS AND MITIGATION MEASURES

This section contains the evaluation of potential environmental impacts associated with the proposed project related to noise. The section identifies the standards of significance used in evaluating the impacts, the methods used in conducting the analysis, and a detailed evaluation of impacts for the proposed project and any potential future expansion.

### Significance Criteria

Based on Appendix G of the CEQA Guidelines; applicable plans, policies, and/or guidelines described above; and agency and professional standards, the proposed project would cause a significant impact related to noise and vibration if the results would:

- Expose people to or generate noise levels in excess of standards established in the local General Plan or noise ordinance, or applicable standards of other agencies;
- Expose people to or generate excessive groundborne vibration or groundborne noise levels;
- Cause a substantial permanent increase in ambient noise levels in the project vicinity above levels existing without the project;
- Cause a substantial temporary or periodic increase in ambient noise levels in the project vicinity above levels existing without the project;
- For a project located within an airport land use plan area, or, where such a plan has not been adopted, in an area within two miles of a public airport or public use airport, expose people residing or working in the area to excessive noise levels; or
- For a project located in the vicinity of a private airstrip, expose people residing or working in the project area to excessive noise levels.

The project's short term construction impacts and long term operational impacts on the ambient noise environment would be considered substantial if it would expose sensitive receptors or other identified land uses to noise levels in excess of regulatory standards or codes. In addition to concerns regarding the absolute noise level that might occur when a new source is introduced into an area, it is also important to consider the existing ambient noise environment. If the ambient noise environment is quiet and the new noise source greatly increases the noise exposure, even though a criterion level might not be exceeded, an impact may occur.

For both construction and operational noise, a "substantial" noise increase can be defined as an increase in noise levels to that which causes interference with activities normally associated with established nearby land uses during the day and/or night. One indicator that noise could interfere with daytime activities normally associated with residential land uses (for example) would be speech interference; whereas, an indicator that noise could interfere with nighttime activities normally associated with residential uses would be sleep interference. This analysis, therefore, uses the following criteria to define whether a temporary or periodic increase in ambient noise levels in the Project vicinity above levels existing without the project would be substantial:

> *Speech Interference*. Speech interference is an indicator of an impact on daytime and evening activities typically associated with residential land uses, but which is also applicable to other similar land uses that are sensitive to excessive noise levels. Therefore, a speech interference criterion, in the context of impact duration and time of day, is used to identify substantial increases in ambient noise levels.
>
> Noise generated by construction equipment could result in speech interference in adjacent buildings if the noise level in the interior of the building were to exceed 45 to 60 dBA[1]. A typical building can reduce noise levels by 25 dBA with the windows closed (U.S. Environmental Protection Agency (EPA) 1974). This noise reduction could be maintained only on a temporary basis in some cases, since it assumes windows must remain closed at all times. Assuming a 25 dBA reduction with the windows closed, an exterior noise level of 70 dBA ($L_{eq}$) adjacent to a building would maintain an acceptable interior noise environment of 45 dBA. It should be noted that such noise levels would be sporadic rather than continuous in nature, because different types of construction equipment would be used throughout the construction process. Therefore, an exterior noise level in excess of 70 dBA $L_{eq}$ during the daytime is used as the threshold for substantial construction noise.
>
> *Sleep Interference*. An interior nighttime level of 35 dBA is considered acceptable (U.S. EPA 1974). Assuming a 25 dBA reduction from a residential structure with the windows closed, an exterior noise level of 60 dBA adjacent to the building would maintain an acceptable interior noise environment of 35 dBA. An exterior threshold of 60 dBA $L_{eq}$ is a reasonable threshold for short term impacts resulting from construction activities. With windows open, a typical house achieves an approximately 15-dBA reduction and, therefore, an exterior noise level of 50 dBA ($L_{eq}$) would be required to maintain an acceptable interior noise environment of 35 dBA. An exterior threshold of 60 dBA $L_{eq}$ is a reasonable threshold for short term impacts resulting from long term operation of the Project.

The duration of exposure at any given noise-sensitive receptor is one consideration in determining an impact's significance. For example, this analysis generally assumes that temporary construction noise that occurs during the day for a relatively short period of time would not be significant. In addition, this analysis assumes that most people of average sensitivity that live in suburban or rural agricultural environments are accustomed to a certain amount of construction activity or heavy equipment noise from time to time. Therefore, for the purposes of this analysis, temporary exposure to construction noise levels that exceed the daytime speech interference threshold would not be considered to result in a substantial temporary increase in ambient noise levels if the duration is two weeks or less.

[1] For indoor noise environments, the highest noise level that permits relaxed conversation with 100 percent intelligibility throughout the room is 45 dBA. Speech interference is considered to become intolerable when normal conversation is precluded at three feet, which occurs when background noise levels exceed 60 dBA.

A numerical threshold to identify the point at which a vibration impact occurs has not been identified by local jurisdictions in the applicable standards or municipal codes. In the absence of local regulatory significance thresholds for vibration from construction equipment, it is appropriate to use the California Department of Transportation (Caltrans) identified PPV thresholds for risk of architectural damage to older residential dwellings, which is 0.30 in/sec. It is also appropriate to use the Caltrans identified PPV thresholds for perceptibility for long term operational vibration, which is 0.10 in/sec (Caltrans, 2013).

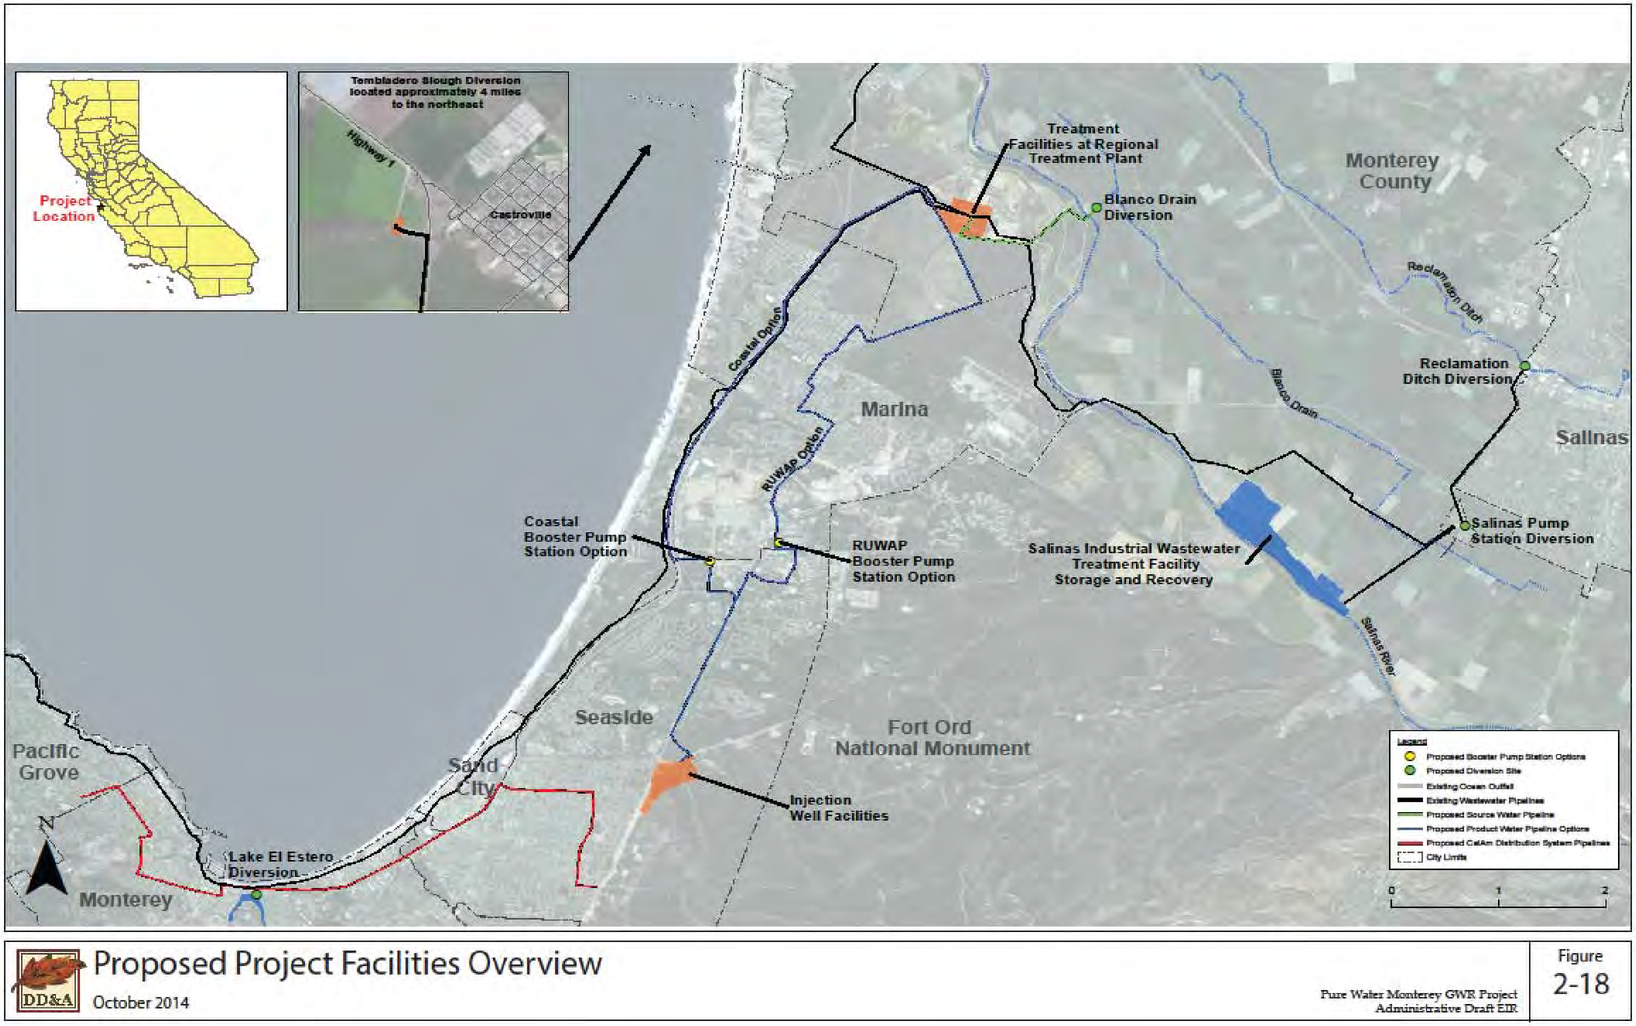
Regarding the last two significance criteria, because the GWR Project would not involve the development of noise-sensitive land uses that would be exposed to excessive aircraft noise, there would be no impacts associated with these criteria. Therefore, impacts associated with aviation noise are not addressed further in this Environmental Impact Report.

The noise and vibration impact assessment evaluates short-term impacts associated with construction of the GWR Project. It also assesses long-term operational impacts (i.e., those resulting from operation of the AWT, booster pump, injection well/back-flush facilities, the diversion sites, and the Salinas Treatment Facilities). The impact discussion analyzes substantial increases in ambient noise levels in the vicinity of the facility sites. In addition, this assessment uses local noise standards and applicable daytime exceptions as the basis for significance thresholds related to "established" noise standards. The assessment of potential noise impacts was conducted using information on existing ambient noise levels and the anticipated noise that would be produced during construction and operation of the Project. The assessment of vibration impacts was conducted using information on anticipated vibration during construction and operation of the Project.

For the purposes of this analysis, only construction noise is considered under the criterion that addresses temporary or periodic increase in ambient noise. Periodic noise increases are defined herein as intermittent or short-term and only construction activities are consistent with this definition.

For clarity and efficiency, the following discussion of impacts and mitigation measures is organized by the action that causes the impact, these being construction noise, construction vibration, and operational noise and vibration. Each impact discussion addresses applicable checklist questions and presents measures to mitigate significant impacts that are identified. Figure 2-10 of the Project Description is included for reference purposes.

## Figure: Facilities Overview



**Impact 1: Construction activity would violate standards established in the local general plans or noise ordinances, and/or would adversely affect nearby sensitive receptors.**

Construction activities would occur intermittently at several locations throughout northern Monterey County within a period of approximately 18-20 months. Such activities would result in the generation of noise associated with site preparation and building of each component of the project. The noise levels generated during construction of the project would vary during the construction period, depending upon the construction phase and the types of construction equipment used.

High noise levels would be created by the operation of heavy-duty trucks, backhoes, bulldozers, excavators, front-end loaders, compactors, cranes, pavers, and other heavy-duty construction equipment. Operating cycles for these types of construction equipment would involve fluctuations in power cycles that result in variations in noise levels, where as other equipment such as directional drill rigs typically operate at a continuous level.

Construction noise levels were calculated using the Federal Highway Administration's Roadway Construction Noise Model (RCNM). The maximum and hourly average noise levels for each phase of construction at the several project construction components are presented in Table 13. In some instances, maximum instantaneous noise levels are calculated to be slightly lower than hourly average noise levels. This occurs because the model calculates the maximum instantaneous noise level resulting from the single loudest piece of construction equipment operating during each construction phase. Hourly average noise levels add together multiple pieces of construction equipment, which results in hourly average noise levels that can be slightly higher than maximum instantaneous noise levels during construction phases involving several pieces of equipment. Construction equipment noise levels were modeled at a distance of 50 feet from the center of the construction site, typical of the distance that the vast majority of receptors would be located from project construction activities conducted along the project corridor. From these source data, calculations were made to estimate construction noise levels at receptors within 50 feet of the construction site or at more distant receptors assuming that the noise attenuation rate was 6 dBA for each doubling of distance from the source where the distance is over roadways and 7.5 dBA for each doubling of distance from the source where the distance is over fields.

Truck trips generated by project construction would be dispersed throughout the day and over the local road network, and commute trips by construction workers would primarily occur before and after project truck trips occur. Daily transportation of materials and construction workers would not be a substantial source of traffic noise levels along local roadways serving the project area.

**TABLE 13 Construction Equipment Noise Levels Modeled at 50 feet**

| Project Component | Duration | Construction Activities | $L_{max}$ | $L_{eq}$ |
|---|---|---|---|---|
| Treatment Facilities at the Regional Treatment Plant | 21 Months | Site preparation | 82 | 79 |
| | | Grading/Excavation | 85 | 87 |
| | | Building Exterior | 84 | 86 |
| | | Paving | 85 | 87 |
| Salinas Pump Station Site | 5 Months | Site Preparation | 84 | 80 |
| | | Grading/Excavation | 84 | 83 |
| | | Trenching, Grading, Install Valves/Piping | 90 | 86 |
| Salinas Industrial Wastewater Treatment Facility—Storage and Recovery | 13 Months | Construction of Facilities and Slip-lining | 91 | 89 |
| Reclamation Ditch Diversion Site | 5 Months | Construction of Facilities and Pipelines (Trenching) | 90 | 86 |
| Tembladero Slough Diversion Site | 5 Months | Construction of Facilities and Pipelines (Trenching), including vibratory driving | 101 | 94 |
| Blanco Drain Diversion Site | 9 Months | Construction of Facilities and Pipelines (Trenching) | 90 | 87 |
| Lake El Estero Diversion Site | 3 Months | Demolition | 90 | 83 |
| | | Site Preparation | 78 | 74 |
| | | Grading/Excavation | 84 | 81 |
| | | Trenching | 90 | 86 |
| | | Paving | 83 | 78 |
| Product Water Conveyance—Pipeline | 15 Months | Pipeline Installation (250 feet/day for roadways, 400 feet/day open areas) | 85 | 87 |
| Product Water Conveyance—Booster Pump Station Sites | 12 Months | Structural work requiring heavy equipment will be completed in 2 to 3 months. | 85 | 87 |
| Injection Well Facilities (including back-flush basin) | 20 Months | Site Preparation | 82 | 81 |
| | | Grading/Excavating | 85 | 85 |
| | | Deep Injection Wells | 85 | 87 |
| | | Vadose Zone Wells | 85 | 85 |
| | | Monitoring Well | 85 | 86 |
| | | Backflush Pipes and Basin | 85 | 85 |

Regional Treatment Plant: New facilities are proposed for construction at the RTP site in a northern portion of Monterey County, north of the city limits of Marina. Construction activities would include cutting, laying, and welding pipelines and pipe connections; pouring concrete footings for foundations, tanks, and other support equipment; constructing walls and roofs; assembling and installing advanced treatment process components; installing piping, pumps, storage tanks, and electrical equipment; testing and commissioning facilities; and finish work such as paving, landscaping, and fencing the perimeter of the site. A residence to the northwest is in Monterey County and residences to the southwest are in the City of Marina. Maximum noise levels generated by construction activities at the RTP would reach 85 dBA $L_{max}$ and 87 dBA $L_{eq}$ at a distance of 50 feet. As shown in Table 14, the source noise level would be attenuated due to distance resulting in noise levels up to 39 dBA at a distance of 1 mile and up to 38 dBA at 5,400 feet, which are the distances to the closest sensitive receptors. Construction noise levels would not exceed the daytime speech interference or nighttime sleep disturbance thresholds at the nearest residences.

**TABLE 14 Maximum Construction Noise Levels – Regional Treatment Plant**

| Construction Activity Source | Receptors | Distance to Receptor | $L_{max}$ | $L_{eq}$ |
|---|---|---|---|---|
| Construction of New Facilities (Grading/Excavating) | Monte Road Residence | 5,260 feet/1 mile (northwest) | 35 | 39 |
| | Cosky Drive Residences | 5,400 feet (southwest) | 34 | 38 |

Note: The noise attenuation rate is assumed to be approximately 6 dBA for each doubling of distance from the source where the distance is over and/or along roadways and developed areas and would be approximately 7.5 dBA for each doubling of distance from the source where the distance is over fields.

In addition, modifications to the existing Salinas Valley Reclamation Plant are proposed in order to enable increased use of tertiary treated wastewater for crop irrigation during winter months. The proposed modifications include new sluice gates, a new pipeline between the existing inlet and outlet structures within the storage pond, chlorination basin upgrades, and a new storage pond platform. All of the modifications would occur within the existing Salinas Valley Reclamation Plant footprint. (See **Section 2.8.2** for further details.) Construction activities would include cutting, laying, and welding pipelines and pipe connections; pouring concrete footings for foundations, and other support equipment; installing piping, sluice gates and electrical equipment; testing and commissioning facilities; and finish work such as repairing the existing storage pond lining. Construction activities related to the Salinas Valley Reclamation Plant Modifications are expected to occur over nine months during normal daytime hours, 7:00 AM to 6:00 PM.

The project site is located within the unincorporated area of Monterey County. Some of the proposed construction equipment that would be required to build the facilities was modeled to result in noise levels at or above 85 dBA at 50 feet, but no residences are within 2,500 feet so construction noise would be in conformance with the Monterey County Code Section 10.60.030. Construction noise impacts would be less than significant.

Section 10.60.040 of the County Code applies to nighttime noise, in which it is prohibited to make, assist in making, allow, continue, create, or cause to be made any loud and unreasonable sound any day of the week from 10:00 PM to 7:00 AM that exceeds 65 dBA $L_{max}$ or 45 dBA $L_{eq}$ as measured at or outside the property line. Construction noise levels would reach 39 dBA at the nearest receptor during nighttime construction, which is below the 65 dBA $L_{max}$ or 45 dBA $L_{eq}$ noise levels (see Table 4.13-14), and would not result in loud and unreasonable noise, consistent with the intent of the ordinance adopting the regulations. As indicated above for the Reclamation Ditch Diversion, Mitigation Measure NV-1b will ensure consistency with General Plan Policy S-7.10 regarding construction equipment, and the policy also allows construction limits to be waived for public convenience. The proposed facilities include improvements to the existing treatment facilities in order to provide additional agricultural irrigation water via the Castroville Seawater Intrusion Project, and commercial agricultural operations are exempt from the provisions of Section 10.60.040 of the County Code.

<u>Salinas Pump Station:</u> New facilities at the Salinas Pump Station are proposed for construction at a southwest portion of The City of Salinas and would include diversion structures and short pipelines to re-direct urban runoff, storm water, and agricultural wash water to the RTP for advanced water treatment. Construction activities at this site would include minor grading, demolition, and installation of a wet well/diversion structure and short pipeline segments. Typical construction hours would be from 7:00 a.m. to 8:00 p.m., Monday through Saturday, although temporary construction connections will be monitored at night because the wastewater will continue to be diverted. The site is surrounded by unincorporated agricultural lands in Monterey County. Three distant residences to the north, west, and south are in Monterey County and distant residences to the east are in the City of Salinas. Maximum noise levels generated by construction activities at the Salinas Pump Station are calculated to reach 90 dBA $L_{max}$ and 86 dBA $L_{eq}$ at a distance of 50 feet. The source noise level would be attenuated due to distance, resulting in noise levels ranging from 49 dBA $L_{max}$ and 45 dBA $L_{eq}$ at a distance of 2,200 feet to up to 54 dBA $L_{max}$ and 50 dBA $L_{eq}$ at 1,400 feet, which is the distance to the closest sensitive receptor (i.e., residence), as indicated in Table 15. Construction noise levels would not exceed the daytime speech interference or nighttime sleep disturbance thresholds at the nearest residences.

**TABLE 15 Maximum Construction Noise Levels – Salinas Pump Station**

| Construction Activity Source | Receptors | Distance to Receptor | $L_{max}$ | $L_{eq}$ |
|---|---|---|---|---|
| Construction of Diversion Structures and Pipelines. (Trenching/Piping) | Farmhouse Residences | 1,400 feet (north) | 54 | 50 |
| | | 1,500 feet (west ) | 53 | 49 |
| | | 1,700 – 2,000 feet (south) | 50 – 52 | 46 – 48 |
| | Salinas Residences | 2,200 feet (east) | 49 | 45 |

Note: The noise attenuation rate is assumed to be approximately 7.5 dBA for each doubling of distance from the source where the distance is over fields.

The City of Salinas Zoning Ordinance (see Table 7) indicates a maximum allowable nighttime noise level 55 dBA in a residential zone. The nighttime sleep disturbance significance threshold for construction noise is 60 dBA $L_{eq}$. Noise levels as a result of proposed construction activity for the Salinas Pump Station would not exceed standards set forth by the City of Salinas or the sleep disturbance threshold. No nighttime noise-generating construction is planned at this site. Therefore, short-term construction noise impacts at this Project site would be less than significant.

Lake El Estero Diversion: New facilities at El Estero would include either a column pump or a gravity system and motorized valve, and short connecting pipelines. The improvements would be in the existing structure or underground. Pavement demolition, trenching and installation of new pumps/pump motors, electrical facilities, and flow meters would all occur below grade using only equipment delivery trucks, loaders, and backhoes. Construction activities at these sites would occur only within typical working hours and would take less than one month.

The Lake El Estero facility and the nearest sensitive receptors southeast of the facility are in the City of Monterey. The site lies within the El Estero recreation area. Maximum noise levels generated by construction activities at El Estero are calculated to reach 90 dBA $L_{max}$ and 86 dBA $L_{eq}$ during the loudest construction phase at a distance of 50 feet. The source noise level would be attenuated due to distance, resulting in noise levels up to 70 dBA at a distance of 500 feet and 73 dBA at 350 feet, which is the distance to the closest sensitive receptor, as indicated in Table 16.

**TABLE 16 Maximum Construction Noise Levels – Lake El Estero Diversion**

| Construction Activity Source | Receptors | Distance to Receptor | $L_{max}$ | $L_{eq}$ |
|---|---|---|---|---|
| Construction of Facilities and Pipelines. (Trenching) | Monterey Bay Lodge | 350 feet (east-southeast) | 73 | 69 |
| | Residence (near First St. and Camino Aguajito) | 500 feet (southeast) | 70 | 66 |

Construction noise levels identified in Table 16 (above) would be below the significance threshold for speech interference at the nearby sensitive receptors. The City of Monterey has not established quantitative construction noise limits. Short-term construction noise impacts at these residences would be less than significant because noise levels are below daytime thresholds. Construction of new facilities at Lake El Estero Diversion site would occur Monday through Saturday, 7 a.m. to 8 p.m., and would take up to three months to complete. Construction activities after 7 p.m. would conflict with City regulations, although a permit may be issued by the Zoning Administrator for construction activities outside hours specified in the City's Municipal Code. .

<u>Product Water Conveyance Pipeline Alignment Options:</u> The Proposed Project would include construction of a pipeline to convey the advanced treated product water from the proposed AWT Facility to the Seaside Groundwater Basin for injection, along one of two potential pipeline alignments. One option would generally follow the RUWAP recycled water pipeline alignment through the City of Marina, CSUMB, and the City of Seaside. The other option, referred to as the Coastal Alignment, would follow in parallel with a portion of the proposed new CalAm Monterey Peninsula Water Supply Project desalination product water pipeline along the eastern side of the Transportation Agency of Monterey County (Transportation Agency) unused railroad tracks. The southern portion of the Coastal Alignment would also be located in the former Fort Ord within the rights of way of Second Avenue, Lightfighter Drive, and General Jim Moore Boulevard in the City of Seaside.

For the purpose of modeling construction noise, the location of the construction noise source (acoustic center) is assumed to be the center of the Area of Potential Effect as displayed in the Draft Area of Potential Effect Maps (DD&A, 2014).

***RUWAP Alignment***

The RUWAP alignment and adjacent sensitive receptors are described the Setting section of this report. Following the pipeline alignment from north to south, the first sensitive receptors are residences along Quebrada Del Mar Road and Crescent Avenue in the City of Marina. The alignment continues along Carmel Avenue, Vaughn Avenue, Reindollar Avenue, California

Avenue to Patton Parkway. These receptors would be located approximately 25 to 50 feet from the construction activities.

The RUWAP alignment enters the former Fort Ord within CSUMB and continues south of Patton Parkway along California Avenue to 5th Avenue, and continues south along 5th Avenue to the Booster Pump Station located adjacent to the City of Marina Corp Yard. No sensitive receptors border the alignment between Patton Parkway and the Booster Pump Station. CSUMB's Strawberry Apartments housing is located within 500 feet of the RUWAP alignment where it approaches the Booster Pump Station.

From the Booster Pump Station, the RUWAP alignment continues south along 5th Avenue and then, entering the City of Seaside, heads east along Inter-Garrison Road passing the CSUMB student dining halls and student center. The alignment heads south at 5th Avenue passing classroom buildings and the campus library. After passing the library, the alignment heads south and then west through open space connecting to General Jim Moore Boulevard south of the Veterans Administration Monterey Clinic. The alignment continues southward along General Jim Moore Boulevard and passes CSUMB outdoor sports/recreation areas, crossing Lightfighter Drive, where the Coastal Alignment would join the RUWAP alignment.

**TABLE 17 Maximum Construction Noise Levels – RUWAP Alignment**

| Alignment Segment (Jurisdiction) | Receptors | Distance to Receptor (feet) | $L_{max}$ (dBA) | $L_{eq}$ (dBA) |
|---|---|---|---|---|
| Quebrada Del Mar Road to Patton Parkway (Marina) | Residences | 25 | 91 | 93 |
| | | 50 | 85 | 87 |
| Patton Parkway to Booster Pump Station (Marina) | CSUMB Housing | 500 | 65 | 57 |
| 5th Avenue to Lightfighter Drive (Seaside) | CSUMB Dining, Student Center, Classrooms | 125 | 77 | 79 |
| | CSUMB Library | 65 | 83 | 85 |
| | Veterans Administration Monterey Clinic | 240 | 71 | 73 |
| Lightfighter Drive to Injection Wells/Back-flush Facility Site (Seaside) | 6th Division Road Residences | 250 | 71 | 73 |
| | 4th Army Road Residences | 210 | 73 | 75 |
| | Post Chapel<br><br>Porter Youth Center | 85 | 80 | 82 |
| | Stillwell Elementary School | 225 | 73 | 75 |
| | Residences between Normandy Road and Coe Avenue (west) | 110 | 78 | 80 |
| | Residences between Normandy Road and Coe Avenue (west) | 90 | 80 | 82 |
| | Seaside Middle School | 280 | 70 | 72 |

Note: The noise attenuation rate is assumed to be approximately 6 dBA for each doubling of distance for pipeline construction.

Both the Coastal and RUWAP Alignment options continue southward on General Jim Moore Boulevard passing residences, the Post Chapel, Stillwell Elementary School, and the Porter Youth Center at Normandy Road. South of Normandy Road, the Alignment passes residences, golf courses, and Seaside Middle School on its way to the Injection Well Facilities site.

Noise levels resulting from the construction of the Coastal Alignment exceeding 70 dBA $L_{eq}$ for more than two weeks would represent a significant nuisance to nearby residences or other sensitive receptors. Noise exceeding 60 dBA for 25 percent of an hour at any receiving property in the City of Marina would violate City of Marina Code.

The installation of the pipeline would occur at a rate of 250 to 400 feet per day. Pipeline trenching activities would proceed along the project alignment at a rate of 1,250 to 2,000 feet per five working days; approaching and departing any one receptor location over a fairly short duration. Assuming a source noise level of up to 87 dBA $L_{eq}$ at a distance of 50 feet, and an attenuation rate of 6 dBA per doubling of distance between the noise source and receptor, pipeline construction activities occurring within 350 feet (in either direction) of a sensitive receptor would yield noise levels greater than 70 dBA $L_{eq}$. As such, the construction noise resulting from proposed pipeline trenching activities at any one location along the alignment would be limited to four days or less. Construction noise would last for no longer than four days at any one location, which would not be considered a significant impact.

Daytime work shift times would violate both Marina and Seaside regulations that prohibit construction after 7:00 p.m. on weekdays and before 9 a.m. on Saturdays. However, section 9.24.050 of the Marina Municipal Code and section 9.12.040D of the Seaside Municipal Code exempt activities on or in publicly owned property and facilities, or by public employees or their franchisees, while in the authorized discharge of their responsibilities, provided that such activities have been authorized by the owner of such property or facilities or its agent or by the employing authority. Construction noise levels may exceed the levels specified in the City of Marina code (exceeding 60 dBA for 25 percent of an hour). The impact would be reduced to a less-than-significant level through implementation of Mitigation Measures 1b, 1c, 1d, 1e, and 1h.

***Coastal Alignment***

The Coastal Alignment enters the City of Marina along the west side of Del Monte Boulevard. Between Marina Green Drive and Legion Way, the alignment would be located about 150 feet west of residences along Del Monte Boulevard. South of Legion Way to Beach Road, residences are located both west (as close as 115 feet) and east (150 feet) of the alignment. South of Beach Road, residential land uses are located about 200 feet east of the alignment and the Marina Library is located about 220 feet to the west. The Superior Court of California, Marina Division, located north of Reservation Road, is approximately 150 east of the alignment.

South of Reservation Road, residences are located as near as approximately 80 feet of the Coastal Alignment to Palm Avenue. South of Palm Avenue, the pipeline would be approximately 100 feet east of play fields associated with the Marina Del Mar Elementary School and would be approximately 350 feet east of the nearest building associated with this elementary school.

Residences along Marina Drive are located as near as approximately 135 feet west of the Coastal Alignment.

The Coastal Alignment would continue south, under the Highway 1 overpass, past MRWPCA's Fort Ord Pump Station along the east side of the Transportation Agency's railroad corridor south to Divarty Street. From this point, the Coastal Alignment would cease to parallel the proposed CalAm Monterey Peninsula Water Supply Project pipeline alignment. There are no sensitive receptors along this segment. The GWR Coastal Alignment would cross under Highway 1Highway 1 at the Divarty Street underpass. The pipeline would follow Divarty Street to Second Avenue, where the Coastal option for the Booster Pump Station would be located. Land uses along Second Avenue include unoccupied (abandoned and dilapidated) buildings and open land with some trees and natural vegetation. Immediately east of the Booster Pump Station sites (on the other side of Second Avenue) are acres of parking lot areas with no vegetation. From the proposed Booster Pump Station site, the pipeline would turn south and follow on the west side of Second Avenue to Lightfighter Drive. At the intersection of Second Avenue and Lightfighter Drive the pipeline would be constructed under Lightfighter Drive by either directional drilling or bore and jack techniques to avoid disruption to this main thoroughfare. From this intersection the alignment would turn eastward and would be constructed on the south side of the Lightfighter Drive roadway, but off the pavement, up to the intersection with General Jim Moore Boulevard. The pipeline would follow the southbound ramp from Lightfighter Drive onto General Jim Moore Boulevard where it would merge to the same alignment as the RUWAP alignment. There are no sensitive receptors in the vicinity of the Coastal alignment south of the Booster Pump Station site until it joins the RUWAP alignment.

Both the RUWAP and Coastal Alignment options continue southward on General Jim Moore Boulevard passing residences, the Post Chapel, Stillwell Elementary School, and the Porter Youth Center at Normandy Road. South of Normandy Road, the Alignment passes residences, golf courses, and Seaside Middle School on its way to the Injection Well Facilities site.

**TABLE 18 Maximum Construction Noise Levels – Coastal Alignment**

| Alignment Segment (Jurisdiction) | Receptors | Distance to Receptor (feet) | $L_{max}$ (dBA) | $L_{eq}$ (dBA) |
|---|---|---|---|---|
| Marina Green to Legion Way (Marina) | Residences | 150 | 75 | 77 |
| Legion Way to Beach Road (Marina) | Residences | 115 | 78 | 80 |
| | Residences | 150 | 75 | 77 |

Note: The noise attenuation rate is assumed to be approximately 6 dBA for each doubling of distance for pipeline construction.

Noise levels resulting from the construction of the Coastal Alignment exceeding 70 dBA $L_{eq}$ for more than two weeks would represent a significant nuisance to nearby residences or other sensitive receptors. The installation of the pipeline would occur at a rate of 250 to 400 feet per day. Pipeline trenching activities would proceed along the project alignment at a rate of 1,250 to 2,000 feet per five working days; approaching and departing any one receptor location over a fairly short duration. Assuming a source noise level of up to 87 dBA $L_{eq}$ at a distance of 50 feet, and an attenuation rate of 6 dBA per doubling of distance between the noise source and receptor, pipeline construction activities occurring within 350 feet (in either direction) of a sensitive receptor would yield noise levels greater than 70 dBA $L_{eq}$. As such, the construction noise nuisance resulting from proposed pipeline trenching activities at any one location along the alignment would be limited to four days or less and thus would not result in a significant noise impact.

Daytime work shift times would violate both Marina and Seaside regulations that prohibit construction after 7:00 p.m. on weekdays and before 9 a.m. on Saturdays. However, section 9.24.050 of the Marina Municipal Code and section 9.12.040D of the Seaside Municipal Code exempt activities on or in publicly owned property and facilities, or by public employees or their franchisees, while in the authorized discharge of their responsibilities, provided that such activities have been authorized by the owner of such property or facilities or its agent or by the employing authority. Construction noise levels may exceed the levels specified in the City of Marina code (exceeding 60 dBA for 25 percent of an hour). The impact would be reduced to a less-than-significant level through implementation of Mitigation Measures 1b, 1c, 1d, 1e, and 1h.

<u>New Booster Pump Station Sites:</u> The proposed new Booster Pump Station (located at one of two locations based on the selected alignment) would receive flow from the Product Water Conveyance Pipeline and pump the product water into one of the two proposed alternative alignments that merge to a single alignment along General Jim Moore Boulevard. Construction crews would prepare the pump station sites by removing vegetation and grading the sites to create a level work area. Construction activities would include excavations for wet wells, installing shoring and forms, pouring concrete footing for foundations; assembling and installing piping, pumps, and electrical equipment; constructing concrete enclosures and roofs; and finish work such as paving, landscaping, and fencing the perimeter of the pump station sites. One Booster Pump Station option would be located along the RUWAP alignment in the City of Marina. The nearest sensitive receptors are residents of the CSUMB campus housing located west of the pump station site and a classroom building southeast of the site. Maximum noise levels generated by structural work at RUWAP Booster Pump Station Option are calculated to reach 85 dBA $L_{max}$ and 87 dBA $L_{eq}$ during the loudest construction phase at a distance of 50 feet.

The source noise level would be attenuated due to distance, resulting in noise levels of up to 66 dBA $L_{max}$ and 68 dBA $L_{eq}$ at a distance of 450 feet and up to 63 dBA $L_{max}$ and 65 dBA $L_{eq}$ at 650 feet, as indicated in Table 19. This attenuation calculation is conservative because it does not take into account any additional attenuation that may occur due to topography, vegetation, nor buildings or fences between source and receptor. The RUWAP Booster Pump Station is located at a lower topographic area than nearby sensitive receptors and is surrounded by trees.

**TABLE 19 Maximum Construction Noise Levels – Booster Pump Station RUWAP Option**

| Construction Activity Source | Receptors | Distance to Receptor | $L_{max}$ | $L_{eq}$ |
|---|---|---|---|---|
| Booster Pump Structural Work. (Heavy Equipment) | Classroom Building | 450 feet (southeast) | 66 | 68 |
| | Campus Housing (Strawberry Apartments) | 650 feet (west) | 63 | 65 |

Construction noise levels identified in Table 19 above would be below the speech interference threshold of 70 dBA $L_{eq}$. Noise exceeding 60 dBA for 25 percent of an hour at any receiving property in the City of Marina would violate City of Marina Code. Although, construction noise levels may exceed the levels specified in the City of Marina code (exceeding 60 dBA for 25 percent of an hour), it is anticipated that the construction noise would not be considered a significant impact due to the predicted noise levels and short-term duration of project construction activities. The construction noise impact would be reduced to a less than significant level through implementation of Mitigation Measures 1b, 1c, 1d, 1e, and 1h.

The Coastal Booster Pump Station option would be located on CSUMB property along the Coastal alignment within the City of Seaside. There are no residential sensitive receptors in the vicinity of the site. A recreation area is located east of the Booster Pump Station site and a child development center is located about 875 feet northeast of the site and at a lower elevation. The recreation area is on CSUMB property within the City of Seaside while the project and child development center are within the City of Marina. Construction noise source generation would be the same as the RUWAP Booster Pump Station Option. The source noise level would be attenuated due to distance, resulting in noise levels of up to 61 dBA $L_{max}$ and 63 dBA $L_{eq}$ at a distance of 750 feet and up to 60 dBA $L_{max}$ 62 dBA $L_{eq}$ at 875 feet, as indicated in Table 20. As with the RUWAP Booster Pump Station option, these attenuation estimates are conservatively low given the topographic change and structures between source and receptor.

**TABLE 20 Maximum Construction Noise Levels – Booster Pump Station Coastal Option**

| Construction Activity Source | Receptors | Distance to Receptor | $L_{max}$ | $L_{eq}$ |
|---|---|---|---|---|
| Booster Pump Structural Work. (Heavy Equipment) | Recreation Center | 750 feet (east) | 61 | 63 |
| | Child Development Center | 875 feet (northeast) | 60 | 62 |

Construction noise levels identified in Table 20 above would be below the speech interference threshold of 70 dBA $L_{eq}$. Daytime work shift times would violate both Marina and Seaside regulations that prohibit construction after 7:00 p.m. on weekdays and before 9 a.m. on Saturdays. However, section 9.24.050 of the Marina Municipal Code and section 9.12.040D of the Seaside Municipal Code exempt activities on or in publicly owned property and facilities, or by public employees or their franchisees, while in the authorized discharge of their responsibilities, provided that such activities have been authorized by the owner of such property or facilities or its agent or by the employing authority. Construction noise levels may exceed the levels specified in the City of Marina code (exceeding 60 dBA for 25 percent of an hour). The construction noise impact would be reduced to a less than significant level through implementation of Mitigation Measures 1b, 1c, 1d, 1e, and 1h.

Injection Well Facilities Site: The proposed new Injection Well Facilities would be located east of General Jim Moore Boulevard, south of Eucalyptus Road in the City of Seaside, including a total of eight recharge wells (four deep injection wells, four vadose zone wells), monitoring wells, and back-flush facilities. The nearest sensitive receptors are residences located west of General Jim Moore Boulevard and the proposed well sites, back-flush facility, and operations buildings. The deep injection well would be drilled with rotary drilling methods. To construct the back-flush pipeline, the contractor would excavate pipe trenches, spread spoilage on site, import and install bedding material, and lay pipe, backfill and compact trench. A main electrical power supply/transformer and motor control building would be built for PG&E power supply. The following activities will be required to construct the pump motor control and electrical conveyance facilities:

- Excavation, haul spoilage, import and install bedding material, building foundation, trench, place concrete, backfill and compact trench, and finish concrete floor of electrical building;
- Install exterior electrical control cabinets on the paved area at the four clusters of vadose and deep injection wells; and
- For electrical building, construct block walls, install building windows, doors and louvers, then roof and appurtenances, then interior finishes, lighting and HVAC, and electrical equipment and wiring.

The project is within the boundary of former Fort Ord and receptors are within the city limits of Seaside. Maximum noise levels generated the during the loudest construction phase at monitoring well sites are calculated to be 85 dBA $L_{max}$ and 87 dBA $L_{eq}$ at a distance of 50 feet.

This source noise level would be attenuated due to distance, resulting in noise levels of up to 66 dBA $L_{eq}$ at a distance of 500 feet, which is the distance to the closest sensitive receptors (i.e., residences). Maximum construction noise levels generated at deep injection and vadose well sites would be the same as at the monitoring wells. This source noise level would be attenuated due to distance, resulting in noise levels of up to 64 dBA $L_{eq}$ at a distance of 700 feet, which is the distance to the closest sensitive receptor (i.e., residence). Maximum noise levels generated by construction at the back-flush basin site could reach 85 dBA $L_{eq}$ at a distance of 50 feet. This source noise level would be attenuated due to distance, resulting in noise levels of 57 dBA $L_{eq}$ at a distance of 1,200 feet, which is the distance to the closest sensitive receptor (i.e., residence).

Well drilling activity was assumed to occur for 24 hours a day at a noise level of 83 dBA $L_{eq}$ at a distance of 50 feet. These levels were measured during drilling on-site at measurement location ST-1, as shown in Table 12 above, and were higher than levels calculated using RCNM, so the measured levels were used for a credible worst case assessment. The noise level from drilling would be attenuated due to distance resulting in noise levels up to 63 dBA $L_{eq}$ at a distance of 500 feet at the residence nearest to a monitoring well and up to 60 dBA $L_{eq}$ at a distance of 700 feet at the residence nearest to a deep injection or vadose zone well. Table 21 shows worst-case noise levels at nearest noise sensitive receptors to Injection Well Facilities site (including back-flush facility).

**TABLE 21 Maximum Construction Noise Levels – Injection Well Facilities**

| Construction Activity Source | Receptors | Distance to Receptor | $L_{max}$ | $L_{eq}$ |
|---|---|---|---|---|
| Monitoring Well (Paving) | Residence near Gen. Jim Moore Blvd south of San Pablo Ave. | 500 feet (west) | 65 | 66 |
| Deep Injection and Vadose Wells (Paving) | Residence near Gen. Jim Moore Blvd north of San Pablo Ave. | 700 feet (west) | 63 | 64 |
| Back-flush Basin (Grading/Excavating) | Residence along Sandpiper Ct. | 1,200 feet (west) | 57 | 57 |
| Monitoring Well Drilling | Residence near Gen. Jim Moore Blvd south of San Pablo Ave. | 500 feet (west) | 69 | 63 |
| Deep Injection and Vadose Well Drilling | Residence near Gen. Jim Moore Blvd north of San Pablo Ave. | 700 feet (west) | 66 | 60 |

The City of Seaside has not adopted quantitative construction noise limits. Daytime construction activities would not exceed the daytime threshold of 70 dBA $L_{eq}$. Drilling activities during nighttime hours would result in noise levels of up to 63 dBA $L_{eq}$ at receiving properties, exceeding the sleep disturbance threshold of 60 dBA $L_{eq}$ by up to 3 dBA. Daytime work shift times would violate Seaside regulations that prohibit construction after 7:00 p.m. and before 9 a.m. on Saturdays. Therefore, impacts would be significant. Implementation of Mitigation Measures 1a, 1b, 1c, 1d, 1e, and 1f would reduce impacts to a less than significant level.

Reclamation Ditch Diversion Site: New facilities at the Reclamation Ditch Diversion are proposed for construction and would include a wet well/diversion structure, connecting pipelines, flow meter and valves, electrical cabinet, and concrete lining. Construction phases include site preparation, grading, trenching, building of facilities, and paving. Typical construction work hours would be 7:00 a.m. to 6:00 p.m., Monday through Saturday. The site is surrounded by agricultural lands to the west in Monterey County and industrial land uses are to the east in Salinas. One distant residence, located approximately 1,000 feet to the west, is in unincorporated Monterey County. Maximum noise levels generated by construction activities at the Reclamation Ditch Diversion site are calculated to reach 90 dBA $L_{max}$ and 86 dBA $L_{eq}$ at a distance of 50 feet. The source noise level would be attenuated due to distance, resulting in noise levels up to 64 dBA $L_{max}$ and 60 dBA $L_{eq}$ at 1,000-feet, which is the distance to the closest sensitive receptor (i.e., residence). Table 21 shows worst-case noise levels at nearest noise sensitive receptors to the Reclamation Ditch Diversion Site.

Some of the proposed construction equipment that would be required to build the facilities would potentially result in noise levels at or above 85 dBA at 50 feet within 2,500 feet of County residences, which would be an apparent violation of County Code Section 10.60.030. However, given the noise attenuation that would result due to the relatively long distance from the construction site to the residence locations about 1,000 feet away, in addition to existing ambient noise levels from traffic on W. Market Street, short-term construction noise impacts at these residences would be less than significant, although construction noise would violate County Code section 10.60.030, a potentially significant impact that would be less than significant with the implementation of the Mitigation Measures 1c and 1g. Mitigation Measure NV-1b requires that construction equipment have properly operating mufflers and stationary noise equipment be located as far as possible from sensitive receptors, consistent with County General Plan Policy S-7.10. General Plan Policy S-7.10 also indicates that construction shall occur only during times allowed by County ordinance or code unless such limits are waived for public convenience. Compliance with County regulations, unless otherwise waived by the County, would be required that would reduce the impact to a less-than-significant level.

**TABLE 21 Maximum Construction Noise Levels – Reclamation Ditch Diversion**

| Construction Activity Source | Receptors | Distance to Receptor | $L_{max}$ | $L_{eq}$ |
|---|---|---|---|---|
| Construction of Facilities and Pipelines (Trenching) | Monterey County residences | 1,000 feet (west) | 64 | 60 |

Tembladero Slough Diversion: New facilities at the Tembladero Slough Diversion Site are proposed for construction and would include a wet well/diversion structure, connecting pipelines, flow meter and valves, electrical cabinet, and concrete lining. Construction phases include site preparation, grading, trenching, building of facilities, and paving. Typical construction work hours would be 7:00 a.m. to 6:00 p.m., Monday through Saturday. The site is surrounded by agricultural lands in Monterey County with one residential land use to the north and a subdivision beyond Hwy 1 to the east. Maximum noise levels generated by construction activities (particularly vibratory driving) at the Tembladero Slough Diversion site are calculated to reach 101 dBA $L_{max}$ and 94 dBA $L_{eq}$ at a distance of 50 feet. The source noise level would be attenuated due to distance, resulting in noise levels up to 77 dBA $L_{max}$ and 70 dBA $L_{eq}$ at 750-feet, which is the distance to the closest sensitive receptor (i.e., residence). Table 22 shows worst-case noise levels at nearest noise sensitive receptors to Tembladero Slough Diversion construction activities.

Short-term construction noise levels at the nearest residences would be below the significance threshold for speech interference during the day for nearby sensitive receptors. Therefore, temporary noise increases due to construction would not be substantial, and noise impacts at this Proposed Project site would be less than significant. Construction noise could conflict with Monterey County Code Section 10.60.30 because some of the proposed construction equipment that would be required to build the facilities was modeled to result in noise levels above 85 dBA at 50 feet and construction would occur within 2,500 of residences within the unincorporated area of the county. Therefore, construction activities at this site could generate noise levels in excess of local standards, which is considered a significant impact. The impact would be less than significant with the implementation of the Mitigation Measures 1c and 1g. Noise levels would not exceed the speech interference or sleep disturbance thresholds at the residences and would be in accordance with Policy S-7.9 because the construction activities would be limited to daytime hours of Monday through Saturday. Mitigation Measure NV-1b requires that construction equipment have properly operating mufflers and stationary noise equipment be located as far as possible from sensitive receptors, consistent with County General Plan Policy S-7.10. General Plan Policy S-7.10 also indicates that construction shall occur only during times allowed by County ordinance or code unless such limits are waived for public convenience. Compliance with County regulations, unless otherwise waived by the County, would be required that would reduce the impact to a less-than-significant level.

**TABLE 22 Maximum Construction Noise Levels – Tembladero Slough Diversion**

| Construction Activity Source | Receptors | Distance to Receptor | $L_{max}$ | $L_{eq}$ |
|---|---|---|---|---|
| Construction of Facilities and Pipelines (Trenching) | Monterey County residences | 750 feet (north) | 77 | 70 |
| | | 850 feet (east, across Hwy 1) | 76 | 69 |

Blanco Drain Diversion Site: New facilities at the Blanco Drain Diversion are proposed for construction and would include a diversion structure, flow meter and valves, an on-site surge tank, electrical cabinet, concrete lining, and pipeline. Construction phases include grading, trenching, building of facilities, and paving. Typical construction work hours would be7:00 a.m. to 6:00 p.m., Monday through Saturday. The site is surrounded by agricultural lands in Monterey County with an industrial land use (the landfill and Regional Treatment Plant) to the west. Two distant residences, one to the northeast and another to the southeast, are in unincorporated Monterey County. Maximum noise levels generated by construction activities at the Blanco Drain Diversion site are calculated to reach 90 dBA $L_{max}$ and 87 dBA $L_{eq}$ at a distance of 50 feet. The source noise level would be attenuated due to distance, resulting in noise levels up to 56 dBA $L_{max}$ and 53 dBA $L_{eq}$ at 2,400-feet, which is the distance to the closest sensitive receptor (i.e., residence). Table 23 shows worst-case noise levels at nearest noise sensitive receptors northeast of Blanco Drain Diversion construction activities.

Short-term construction noise levels at the nearest residences would be below the significance threshold for speech interference during the day for nearby sensitive receptors. Therefore, temporary noise increases due to construction would not be substantial, and noise impacts at this Proposed Project site would be less than significant. Construction noise could conflict with Monterey County Code Section 10.60.30 because some of the proposed construction equipment that would be required to build the facilities was modeled to result in noise levels above 85 dBA at 50 feet and construction would occur within 2,500 of residences within the unincorporated area of the county. Therefore, construction activities at this site could generate noise levels in excess of local standards, which is considered a significant impact. The impact would be less than significant with the incorporation of the Mitigation Measures 1c and 1g. Noise levels would be consistent with Policy S-7.9 because the construction activities would be limited to daytime hours of Monday through Saturday. Mitigation Measure NV-1b requires that construction equipment have properly operating mufflers and stationary noise equipment be located as far as possible from sensitive receptors, consistent with County General Plan Policy S-7.10. General Plan Policy S-7.10 also indicates that construction shall occur only during times allowed by County ordinance or code unless such limits are waived for public convenience. Compliance with County regulations, unless otherwise waived by the County, would be required that would reduce the impact to a less-than-significant level.

**TABLE 23 Maximum Construction Noise Levels – Blanco Drain Diversion**

| Construction Activity Source | Receptors | Distance to Receptor | $L_{max}$ | $L_{eq}$ |
|---|---|---|---|---|
| Construction of Facilities and Pipelines (Trenching) | Monterey County residences | 2,400 feet (northeast) | 56 | 53 |
| | | 3,000 feet (southeast) | 54 | 51 |

Salinas Industrial Wastewater Treatment Facility Storage and Recovery: Construction of the Salinas Treatment Facility Storage and Recovery component is proposed for two project sites: on-site at the Salinas Treatment Facility and off-site along the existing 33-inch industrial wastewater pipeline that is proposed to be slip-lined. The facilities on-site at the Salinas Treatment Facility would include a recovery pump station, pond #3 pump station, and on-site pipelines. The off-site facilities would include slip-lining the existing 33-inch pipeline with a new smaller diameter pipe. Construction phases for both project components include site preparation, grading, trenching, building of facilities, and paving, all of which would occur within a six-month construction period. Typical construction work hours would be 7:00 a.m. to 8:00 p.m., Monday through Saturday. The site is surrounded by agricultural lands in Monterey County. One distant residence to the southeast is in unincorporated Monterey County. Maximum noise levels generated by construction activities at Salinas Treatment Facility site are calculated to reach 91 dBA $L_{max}$ and 89 dBA $L_{eq}$ at a distance of 50 feet. The source noise level would be attenuated due to distance, resulting in noise levels up to 57 dBA $L_{max}$ and 55 dBA $L_{eq}$ at 2,500-feet, which is the distance to the closest sensitive receptor (i.e., residence). Table 24 shows worst-case noise levels at nearest noise sensitive receptors to Salinas Treatment Facility construction activities.

Some of the proposed construction equipment that would be required to build the facilities was modeled to result in noise levels at or above 85 dBA at 50 feet, which could possibly be a violation of County Code 10.60.030. However, the code does not apply to machines operated in excess of 2,500 feet from an occupied dwelling. The nearest residence is about 2,500 feet away from the site. Given the noise attenuation that would result due to the relatively long distance from the construction site to the nearest residence about 2,500 feet away, in addition to existing ambient noise levels from traffic on Davis Road, short-term construction noise impacts at these residences would be less than significant because it is below the 60 dBA $L_{eq}$ level for daytime speech interference.

**TABLE 24 Maximum Construction Noise Levels – Salinas Treatment Facility Storage and Recovery**

| Construction Activity Source | Receptors | Distance to Receptor | $L_{max}$ | $L_{eq}$ |
|---|---|---|---|---|
| Construction of facilities at the Salinas Treatment Facility and slip-lining existing pipeline | Monterey County residences | 2,500 feet (southeast) | 57 | 55 |

**Mitigation 1:**

a) Contractor specifications shall include a requirement that drill rigs located within 700 feet of noise-sensitive receptors shall be equipped with noise reducing engine housings or other noise reducing technology and the line of sight between the drill rig and nearby sensitive receptors shall be blocked by portable acoustic barriers and/or shields to reduce noise levels such that drill rig noise levels are no more 75 dBA at 50 feet. This would reduce the nighttime noise level to less than 60 dBA $L_{eq}$ at the nearest residence.

b) The construction contractor shall limit all non-well drilling, noise-generating construction activities to between the hours of 7:00 a.m. and 7:00 p.m. on weekdays and between 9:00 a.m. and 7:00 p.m. Saturdays, or as agreed upon by the local jurisdiction.

c) The contractor shall assure that construction equipment with internal combustion engines has sound control devices at least as effective as those provided by the original equipment manufacturer. No equipment shall be permitted to have an un-muffled exhaust.

d) The contractor shall locate all stationary noise-generating equipment (e.g., generators, air compressors) as far from nearby noise-sensitive receptors as possible, and shall muffle and enclose them in temporary sheds, incorporate noise barriers, or implement other noise control measures to the extent feasible. The noise controls shall be sufficient to reduce noise levels during nighttime pipeline installation, drilling and development of injection wells, and pump station construction activities below the threshold of 60 dBA $L_{eq}$ at the nearest residential receptor.

e) Residences and other sensitive receptors within 500 feet of a daytime construction area and within 900 feet of a nighttime construction area shall be notified of the construction schedule in writing, at least two weeks prior to the commencement of construction activities. The notice shall also be posted along the proposed pipeline alignments, near the proposed facility sites, and at nearby recreational facilities. The project contractor shall designate a noise disturbance coordinator who would be responsible for responding to complaints regarding construction noise. The coordinator shall determine the cause of the complaint and ensure that reasonable measures are implemented to correct the problem. A contact number for the noise disturbance coordinator shall be conspicuously placed on construction site fences and included in the construction schedule notification sent to nearby residences. The notice to be distributed to residences and sensitive receptors shall first be submitted to local Building Officials for review and approval, to the MRWPCA and city and county staff as may be required by local regulations.

f) For work within the City of Seaside, the construction contractor shall submit to the MRWPCA and the Seaside Building Official, a “Well Construction Noise Control Plan” for review and approval. The plan shall identify all equipment that will operate at night and all feasible noise control procedures that would be implemented during night-time construction activities. At a minimum, the plan shall specify the noise control treatments that have been incorporated to achieve the noise performance standards contained in Mitigation Measure 1a.

g) The construction contractor shall comply with Monterey County regulations to not generate noise levels above 85 dBA at 50 feet at sites within 2,500 feet of an occupied residence unless approval has been obtained from Monterey County.

h) The construction contractor shall comply with Marina Municipal Code regulations to conduct day-time construction that would produce a noise level of no more than 60 decibels for twenty-five percent of an hour at any receiving property line unless approval has been obtained from the City.

**Significance after Mitigation: Less than Significant.**

**Impact 2: Exposure to, or Generation of, Excessive Groundborne Vibration.** Construction related vibration would not be excessive at nearby land uses.

For structural damage, the Caltrans recommends a vibration limit of 0.5 in/sec PPV for buildings structurally sound and designed to modern engineering standards, 0.3 in/sec PPV for buildings that are found to be structurally sound but where structural damage is a major concern, and a conservative limit of 0.08 in/sec PPV for ancient buildings or buildings that are documented to be structurally weakened.

All buildings in the project vicinity are assumed to be structurally sound, but these buildings may or may not have been designed to modern engineering standards. Vibration impacts would be considered significant if levels from proposed construction activities would exceed 0.3 in/sec PPV at nearby buildings. Vibration levels exceeding 0.3 in/sec PPV could result in cosmetic damage. No ancient buildings or buildings that are documented to be structurally weakened are known to exist along the project corridor.

The construction methods for the proposed project include both open trench installation and trenchless construction methods. Open trench construction activities with the potential of generating perceptible vibration levels would include the removal of pavement and soil, and the compacting of backfill after the new pipeline is installed. Trenchless methods such as jack-and-bore, drill-and-burst, horizontal directional drilling, and/or microtunneling would be employed where it is not feasible or desirable to perform open-cut trenching. Table 22 summarizes typical vibration levels associated with varying pieces of construction equipment at a distance of 25 feet.

A review of the proposed equipment and the vibration level data provided in Table 22 indicates that, with the exception of impact or vibratory pile driving (not proposed as a construction technique), vibration levels generated by the proposed equipment would be below the 0.3 in/sec PPV criterion used to assess the potential for cosmetic or structural damage to buildings located beyond a distance of 25 feet. The nearest buildings would be a minimum distance of 25 feet from the work areas. Trenchless construction methods results in less vibration than open trench construction activities because the equipment used in these processes are not high-powered vibratory devices, and the depth of the underground tunnel increases the distance between the equipment and structures on the surface and reduces vibration. This is a *less than significant* impact.

**TABLE 25 Vibration Source Levels for Construction Equipment**

| Equipment | | PPV at 25 ft. (in/sec) |
|---|---|---|
| Pile Driver (Impact) | upper range | 1.158 |
| | typical | 0.644 |
| Pile Driver (Sonic) | upper range | 0.734 |
| | typical | 0.170 |
| Clam shovel drop | | 0.202 |

| Loaded trucks | | 0.076 |
| Jackhammer | | 0.035 |
| Small bulldozer | | 0.003 |

Source: Transit Noise and Vibration Impact Assessment, United States Department of Transportation, Federal Transit Agency, Office of Planning and Environment, May 2006.

**Mitigation 2: None required.**

**Impact 3: Operation of the proposed GWR facilities would potentially increase existing noise levels, which could exceed noise level standards and/or result in nuisance impacts at sensitive receptors.**

Sources of noise associated with the operation of the GWR Project would include new pumps and other equipment at the RTP, the Salinas Pump Station, Lake El Estero Diversion Site, new Booster Pump Station, the new Injection Well Facilities, the Reclamation Ditch, Tembladero Slough, Blanco Drain Diversion sites, and the Salinas Industrial Wastewater Treatment Facility Storage and Recovery. Employee traffic and maintenance activities would not be considerable sources of noise as discussed qualitatively below.

*OPERATIONAL TRAFFIC*

Table 2-10 of the Project Description provides a summary of operational traffic for each of the various project components as a result of employee commute trips, maintenance, and delivery of materials to the various pump stations. The project would generate up to 10 employee trips and 2 truck trips per day at the Regional Treatment Plant and fewer trips at all other facilities. Noise generated by employee and truck traffic would not be considerable. Thus, associated impacts would be less than significant.

*MAINTENANCE ACTIVITIES*

Noise that would be associated with plant, pipeline, and other facility maintenance would be short-term and infrequent (less than one trip per day to each component site) resulting from activities that would not result in measureable increases of ambient noise levels in the surrounding area. Impacts related to project maintenance would be less than significant.

*SOURCE WATER DIVERSION AND STORAGE SITES*

*Salinas Pump Station*

New facilities at the Salinas Pump Station Diversion site include diversion structures and short pipelines to re-direct urban runoff, storm water, and agricultural wash water to the RTP for advanced water treatment. No new noise-generating equipment is proposed.

*Salinas Industrial Wastewater Treatment Facility Storage and Recovery Site*

The proposed project includes improvements that would enable the agricultural wash water to be conveyed from the ponds at the Salinas Industrial Wastewater Treatment Facility to the Regional Treatment Plant for recycling. Components of the project include a new pump station, pipeline, on-site piping, SCADA, and a return with valve and meter vaults. No new operations/maintenance staff trips or work would be needed at the site. The only source of noise associated with this component of the project would be a new submersible pump installed in a wet well in pond 3 and a new return pump station near the aeration ponds. As noted above, the sound of the submersible pump would be attenuated and barely audible just outside of the wet well. Operational noise levels would not make a measurable contribution to ambient noise levels at the nearest receptors approximately 2,500 feet southeast of the site.

*Reclamation Ditch Diversion Site*

New facilities at the Reclamation Ditch Diversion site east of Davis Road include improvements to divert water to the Regional Treatment Plant. Components of the project include a wet well/diversion structure, connecting pipelines, flow meter and valve, electrical pump/cabinet, and concrete lining of channel banks. The only source of noise associated with this component of the project would be a new submersible pump installed in the wet well. The submersible pump and associated piping would be installed below grade and submersed in water. The sound of the submersible pump would be attenuated at the water/air interface because the acoustical characteristics of water and air are different given that the density of water is so much greater than the density of air. The noise from the new pump would be barely audible just outside of the wet well in the absence of traffic along Davis Road and inaudible at residences located approximately 1,000 feet away from the Davis Street site along West Market Circle (west), West Rossi Street (northwest), and Nacional Court (south). One truck trip up to three times per week is expected to go to the site creating no change in ambient noise levels.

*Tembladero Slough Diversion*

Improvements to divert water to the Regional Treatment Plant at the Tembladero Slough site include a wet well/diversion structure, connecting pipelines, flow meter and valves, electrical cabinet, and concrete lining of channel banks. Similar to the Reclamation Ditch Diversion site east of Davis Road, the sound of the proposed submersible pump in the wet well would be barely audible just outside of the wet well in the absence of local traffic along Highway 1. No new operations/maintenance staff is expected. Operational noise levels from new noise-generating equipment or vehicle trips would not make a measurable contribution to ambient noise levels resulting from Highway 1 traffic at the nearest receptors along Watsonville Road (750 feet north of the project site) or Merritt Circle (850 feet east of the project site).

*Blanco Drain Diversion Site*

The Blanco Drain Diversion site includes improvements that would allow for the diversion of water to the Regional Treatment Plant for recycling. Components of the project include a wet well/diversion structure, flow meter, valves, and on-site surge tank, connecting pipelines, electrical cabinet, concrete lining of channel banks, and pipelines. No new operations/maintenance staff is expected. The only source of noise associated with this component of the project would be a new submersible pump installed in the wet well. As noted above, the sound of the submersible pump would be attenuated and barely audible just outside of the wet well. Operational noise levels would not make a measurable contribution to ambient noise levels at the nearest receptors approximately 2,400 feet east-northeast of the site along Nashua Road.

*Lake El Estero Diversion Site*

New facilities at El Estero would include either a column pump or a gravity system and motorized valve, and short connecting pipelines. The improvements would be in the existing structure or underground. The small diversion pump would be located within the pump vault that houses two larger pumps. The addition of the new pump would not measurably affect the noise emanating from the pump station.

*TREATMENT FACILITIES AT THE RTP*

Treatment Facilities at the Regional Treatment Plant would include pre-treatment, the AWT Facility, product water pump station; concentrate disposal facilities and SVRP modifications. As previously indicated, modifications to the existing Salinas Valley Reclamation Plant are proposed in order to enable increased use of tertiary treated wastewater for crop irrigation during winter months. The proposed modifications include new sluice gates, a new pipeline between the existing inlet and outlet structures within the storage pond, chlorination basin upgrades, and a new storage pond platform. All of the modifications would occur within the existing Salinas Valley Reclamation Plant footprint and would not include new sound-generating equipment that would affect the community noise environment.

The proposed treatment facilities and brine mixing facility would include several structures. New pipes and pumps will be underground. In the analysis of operational noise, because mechanical equipment noise is constant, the $L_{eq}$ noise level is used to assess operational noises against the thresholds.

The proposed new AWT Facility would have a design capacity of approximately 4.0 mgd of product water. Noise resulting from new facilities would be generated from proposed stationary sources associated with facility operations, including primarily electric water pumps. The pumps have an estimated combined noise level of 108 dBA $L_{eq}$ at a distance of 3 feet. Typical operating conditions would result in pump reference noise levels of approximately 85 dBA $L_{eq}$ at 50 feet assuming the pumps were at grade and not inside an enclosure. There are no other known sources of noise that would measurably increase the noise levels generated by the pumps. A residence to the northwest is in Monterey County and residences to the southwest are in the City of Marina. Maximum noise levels generated by operations at the RTP would be 35 dBA $L_{eq}$ at a distance of approximately 1 mile.

**TABLE 26 Operational Noise Levels – Treatment Facilities at the Regional Treatment Plant**

| Operational Source | Receptors | Distance to Receptor | $L_{eq}$ |
|---|---|---|---|
| New pumps and other process equipment | Monte Road Residence | 5,260 feet/1 mile (northwest) | 35 |
| | Cosky Drive Residences | 5,400 feet (southwest) | 35 |

Note: The noise attenuation rate is assumed to be approximately 7.5 dBA for each doubling of distance from the source where the distance is over fields.

Noise levels as a result of the operation of the proposed Treatment Facilities at the RTP would not exceed the City of Marina or Monterey County noise standards. Noise levels would be substantially below ambient noise levels in the surrounding area, and plant operations would not result in an increase in ambient noise levels that would exceed local standards.

Section 10.60.040 of the County Code applies to nighttime noise, in which it is prohibited to make, assist in making, allow, continue, create, or cause to be made any loud and unreasonable sound any day of the week from 10:00 PM to 7:00 AM that exceeds 65 dBA $L_{max}$ or 45 dBA $L_{eq}$ as measured at or outside property line. As indicated above, noise levels would reach 37 dBA at the nearest sensitive receptor, which is below the 65 dBA $L_{max}$ or 45 dBA $L_{eq}$ noise levels, and would not result in loud and unreasonable noise, consistent with the intent of the ordinance adopting the regulations. Furthermore, the proposed facilities include improvements to the existing treatment facilities in order to provide additional agricultural irrigation water via the Castroville Seawater Intrusion Project, which is indirect support of commercial agricultural operations, which are exempt from the provisions of Section 10.60.040 of the County Code.

*PRODUCT WATER CONVEYANCE*

*Booster Pump Stations*

The proposed new Booster Pump Station would receive flow from the Product Water Conveyance Pipeline and pump the product water into one of the two proposed alternative alignments that merge to a single alignment along General Jim Moore Boulevard. One Booster Pump Station option would be located along the RUWAP alignment in the City of Marina. The nearest sensitive receptors are residents of the CSUMB campus housing located west of the pump station site and a classroom building southeast of the site.

Noise resulting from the Booster Pump Station would primarily result from the operation of electric water pumps. Two nominal 250 hp pumps would be installed, but only one pump would operate at any given time. The estimated operational noise level would be 93 dBA $L_{eq}$ at a distance of 3 feet. Typical operating conditions would result in pump reference noise levels of approximately 70 dBA $L_{eq}$ at 50 feet assuming the pumps were at grade and not inside an enclosure. The additional attenuation provided by locating the pumps below ground and within an enclosure is conservatively estimated to be 20 dBA resulting in pump reference noise levels of approximately 50 dBA $L_{eq}$ at 50 feet. The nearest sensitive receptors are residents of the CSUMB campus housing located west of the pump station site and a classroom building southeast of the site. Maximum noise levels generated by operations at Booster Pump Station RUWAP Option are calculated to result in noise levels of up to 31 dBA $L_{eq}$ at a distance of 450 feet and up to 28 dBA $L_{eq}$ at 650 feet, as indicated in Table 24.

**TABLE 27 Operational Noise Levels – Booster Pump Station RUWAP Option**

| Operational Source | Receptors | Distance to Receptor | $L_{eq}$ |
|---|---|---|---|
| Booster Pump Station RUWAP Option | Classroom Building | 450 feet (southeast) | 31 |
| | Campus Housing (Strawberry Apartments) | 650 feet (west) | 28 |

Noise levels as a result of the operation of Booster Pump Station (RUWAP options) would not exceed the City of Marina noise standards for daytime noise at the nearest classroom buildings or the daytime or nighttime noise standards at the campus housing. Operational noise levels would not make a measurable contribution to ambient noise levels at the nearest receptors.

The Coastal Booster Pump Station option would be located on City of Seaside or CSUMB property at the corner of Divarty Street and 2$^{nd}$ Avenue. There are no residential receptors in the vicinity of the site. A recreation center (gymnasium/workout facility is located east of the Booster Pump Station site and a child development center is located about 875 feet northeast of the site. The recreation center is on CSUMB property within the City of Seaside while the child development center is within the City of Marina. Operational noise generation would be the same as the RUWAP Option. Maximum noise levels generated by operations at Booster Pump Station Coastal Option are calculated to result in noise levels of up to 41 dBA $L_{eq}$ at a distance of 750 feet and up to 40 dBA $L_{eq}$ at 875 feet, as indicated in Table 25.

**TABLE 28 Operational Noise Levels – Booster Pump Station Coastal Option**

| Operational Source | Receptors | Distance to Receptor | $L_{eq}$ |
|---|---|---|---|
| Booster Pump Station Coastal Option | Recreation Center | 750 feet (east) | 41 |
| | Child Development Center | 875 feet (northeast) | 40 |

Noise levels as a result of the operation of Booster Pump Station Coastal Option would not exceed the City of Marina noise standards for daytime or nighttime noise. Operational noise levels would not make a measurable contribution to ambient noise levels at the nearest receptors. No City of Seaside standards currently apply to the Coastal Booster Pump Station due to lack of existing land uses in the vicinity that would be exposed to noise. Future planned land uses in the vicinity may include commercial uses, including restaurants, stores, and movie theaters, that would not be adversely affected by operation of the proposed Coastal Booster Pump Station.

*INJECTION WELL FACILITIES*

The proposed new Injection Well Facilities would be located east of General Jim Moore Boulevard, south of Eucalyptus Road in the City of Seaside, including a total of eight wells (four deep injection wells, four vadose zone wells), monitoring wells, and back-flush facilities, at an area formerly referred to as the Inland Recharge Area. Each injection well would be equipped with a well pump to back-flush the well. The estimated motor size for each pump is approximately 400 hp. The back-flush pumps are the only considerable source of noise from these facilities. The back-flushing rate would be approximately 2,000 gallons per minute (gpm) and would require a well pump and motor. Based on the experience of the Water Management District in the operation of its nearby Aquifer Storage and Recovery wells, back-flushing of each injection well would occur about weekly and would require discharge of the back-flush water to a percolation pond, or back-flush basin, with a capacity of about 300,000 gallons. At this back-flush rate, the pump would operate for about 150 minutes during the daytime.

The 400 hp back-flush pump has an estimated noise level 85 dBA $L_{eq}$ at 50 feet assuming the pumps are at grade and not inside an enclosure. The nearest residences to Deep Injection Well 4 (DIW4) are located 700 feet to the west in Seaside. The maximum noise level, generated by back-flush operations at DIW4, is calculated to be 56 dBA $L_{eq}$ and 46 dBA CNEL, as indicated in Table 25.

**TABLE 29 Operational Noise Levels – Injection Well Facilities**

| Operational Source | Receptors | Distance to Receptor | $L_{eq}$ | CNEL |
|---|---|---|---|---|
| Back-flush pump at the southernmost injection well cluster | Residence near Gen. Jim Moore Blvd north of San Pablo Ave. | 700 feet (west) | 56 | 46 |

Noise levels as a result of the operation of the back-flush pump at DIW4, as well as the remaining wells located further from receptors, would not exceed the City of Seaside noise standard of 65 dBA CNEL.

**Mitigation 3: None required.**

# Regional Treatment Plant Wastewater Flow Projection Report

*This page is intentionally blank.*

June 16, 2014

Mr. Keith Israel
General Manager
Monterey Regional Water Pollution Control Agency
5 Harris Court
Monterey CA 9

Subject: RTP Wastewater Flow Projection Report

Mr. Israel:
This report presents the results of Brezack & Associates Planning, LLC (B&AP) development of forty-year wastewater flow projections to the Regional Treatment Plant (RTP). The purpose of this investigation has been to rationalize, quantify and extrapolate the observations by MRWPCA that influent to the RTP has been decreasing for the last several years.

Key to our analysis was the assistance of several MRWPCA staff including Mr. Robert Holden and Mrs. Jennifer Gonzales to whom we are grateful for their reviews of draft documents and provision of vital data.

Factors contributing to reduced wastewater flows have previously been assumed to include: the economic downturn to the regional economy; the high cost of urban water throughout the Monterey Peninsula; and, increased use of interior water conservation best management practices.

Rather than speculate on the future impact of potential causes, it was agreed that the project would base its forecasts of wastewater flows on the following two key data: population and per capita wastewater generation in the service area. A spreadsheet model was developed using historical population and flow data to produce a range of potential projections through the year 2055.

RTP flow is projected to decrease to a range of 19.2 to 17.1 mgd. After 2030, flows may increase to a range of highs between 24.3 and 22.7 mgd. The model included in this report facilitate MRWPCA's testing of data input values and the development of additional flow scenarios.

Sincerely,

James M. Brezack
President & Project Director

# EXECUTIVE SUMMARY

The Monterey Regional Water Pollution Control Agency (MRWPCA) engaged Brezack & Associates Planning (B&AP) to produce a forty-year projection of wastewater flows to the MRWPCA Regional Treatment Plant (RTP). This report details the development and results of those projections.

MRWPCA staff has observed the trend of decreasing wastewater flows influent to the RTP. If this condition continues, available capacity at the RTP can become a valuable benefit to the service area in the following ways:

- New wastewater treatment capacity that can be allocated to new and planned development projects.
- Wastewater treatment capacity that can be reallocated to member entities with the greatest need.
- Treatment of dry weather flows from storm drains and the reduction or elimination of nuisance discharges.
- Treatment of wet weather flows from storm drains and a decrease in discharges to the ocean and to Areas of Special Biological Significance (ASBS).
- Increases in wastewater and storm water that can be recycled to serve as source waters for agricultural and landscape irrigation and groundwater replenishment.

Accurate predictions of long-term capacity availability at the RTP is a critical first step in planning for these and other benefits.

The estimation of long-range projections in wastewater flows is an imprecise science subject to numerous variables. The longer the planning horizon is, the more difficult it becomes to make reliable projections. Typically, wastewater projections in California are made within the ten-year horizon of a City's General Plan and or the twenty-year horizon of an Urban Water Management Plan. This investigation attempts to estimate projected wastewater flows forty years into the future, past the anticipated build-out of the service area.

Demographics, employment, water use and conservation trends, as well as local and regional economic factors all play a role in determining the volume of wastewater generated by any community. The MRWPCA service area is not a homogenous community that can be easily characterized. The economic and demographic characteristics of each of the twelve communities that comprise the MRWPCA regional wastewater service area results in additional challenges in predicting the total influent flows to the RTP.

Therefore, one important element of this investigation was the development of a simple process to regularly review and update its conclusions. This was done by the preparation of a spreadsheet model presented in Appendix G of this report.

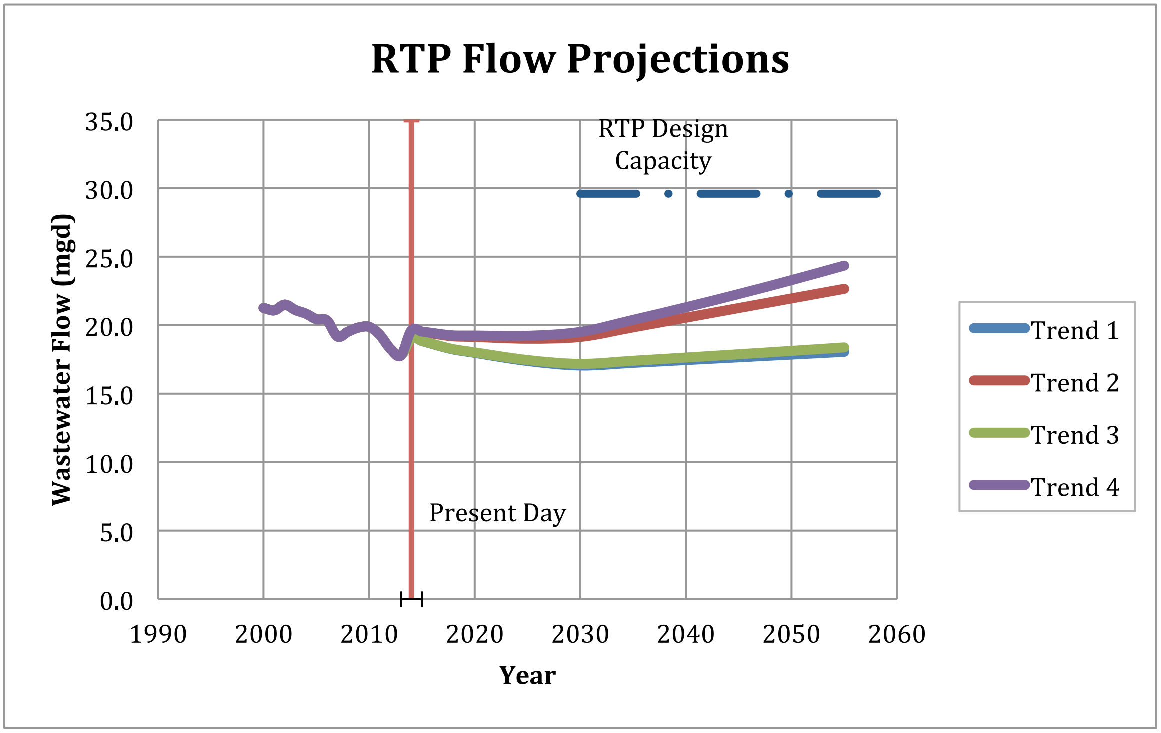
Historical population and wastewater flow data was used to create a spreadsheet model to calculate a range of potential wastewater flow projections. Using recorded pump station data, average wastewater flow generated per person in units of gallons per capita per day (GPCD) was calculated for the years 2000 through 2012. Trends in population and GPCD were projected forward to the year 2055. Wastewater flow projections for each community in MRWPCA's service area were calculated from these trends.

The conclusion of this investigation is that wastewater flows to the RTP are projected to decrease to a minimum value in the year 2030. This decease is predicted as the result of increased water conservation, raising water rates and regional economic factors. Wastewater flows to the RTP may then range between 17.1 and 19.2 mgd. This investigation projected four trends of population growth based on data (Table ES-1). The high RTP wastewater flow trends that may occur in 2055 due to projected population growth are 22.7 and 24.3 mgd. The forty-year projected wastewater flows to the RTP are shown in Figure ES - 1. By 2055, the high trend values of average wastewater flows to the RTP are projected to range from 82% to 77% of design capacity, leaving 23% to 18% capacity availability at the RTP for treatment of additional wastewater, dry weather, or storm water flows.

**Table ES - 1: Description of Population Trends Used to Produce Range of Wastewater Flow Projections**

| Legend Entry | Description |
|---|---|
| Trend 1 | A linear curve is fitted to data from year 2000 to 2012 |
| Trend 2 | A linear curve is fitted to data from year 2006 to 2012 |
| Trend 3 | An exponential curve is fitted to data from year 2000 to 2012 |
| Trend 4 | An exponential curve is fitted to data from year 2006 to 2012 |

**Figure ES - 1: RTP Wastewater Flow Projections**



The following recommendations are made to further refine the wastewater projections for the RTP and the service area communities:

1. Routinely make updates to the flow projections by recording and projecting pump station flows and the populations by community. This should be done on a three to five year cycle.
2. Recalibrate the models as new data becomes available.
3. Use a Geographic Information System (GIS) to refine service area populations and sewershed boundaries to determine precisely any differences in the boundaries of MRWPCA service areas, areas contributing flow to each pump station, and the city and census designated place (CDP) boundaries defined by the U.S. Census Bureau.
4. Conduct wastewater flow monitoring and acquire potable water service connection information at the Seaside and Moss Landing pump stations to validate wastewater flow data.
5. Conduct wastewater flow monitoring for various land use types to acquire flow data per sewer connection by land use type.
6. Consult a demographer with knowledge of regional trends to produce additional population and GPCD projections.

7. Perform a study of the Fort Ord Pump Station, to refine its contributing sewershed. This will allow for the projection of population growth, GPCD decline, and wastewater flow specific to the Ord Pump Station.

# 1 PURPOSE

The Monterey Regional Water Pollution Control Agency (MRWPCA) retained Brezack & Associates Planning (B&AP) to prepare a 40-year projection of wastewater flow from its service area to the Regional Treatment Plant (RTP) in Marina, California. The RTP has a permitted treatment capacity of 29.6 mgd. Influent flow to the RTP has been decreasing over the past several years and is believed to be the result of regional economic conditions and water conservation factors. This report presents the development and results of the 40-year wastewater flow projections to the RTP.

A spreadsheet model was created to calculate future wastewater flows based on service area populations and per capita wastewater generation rates.

MRWPCA manages a regional wastewater system that provides centralized wastewater treatment for cities and communities throughout portions of Monterey County as shown in Figure 1. A network of wastewater pump stations and pressure pipelines convey wastewater to the RTP for treatment and recycling. Figure 2 is a schematic diagram of the relationship between the major service area pumping facilities. Many of the pump stations are located at former wastewater treatment plants and were repurposed when the regional system was developed.

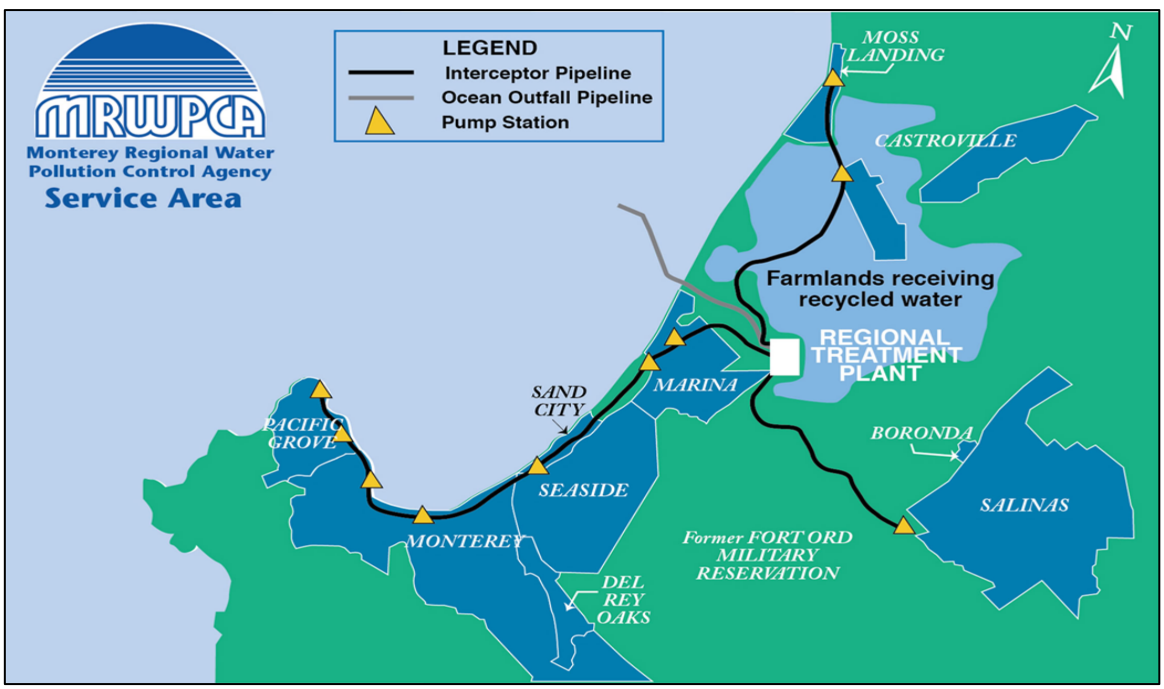


**Figure 1: MRWPCA Service Area**

| Facility Name | Flow Rates (MGD) ADWF | PWWF |
|---|---|---|
| Monterey Interceptor (MI) Flows | 6.7 | 19.8 |
| Salinas Interceptor (SI) Flows | 11.8 | 15.0 |
| Castroville Interceptor (CI) Flows | 0.7 | 2.0 |
| Total RTP Influent Flows to Headworks | 19.2 | 36.8 |
| RTP Permitted Design Flows | 29.6 | 75.6 |

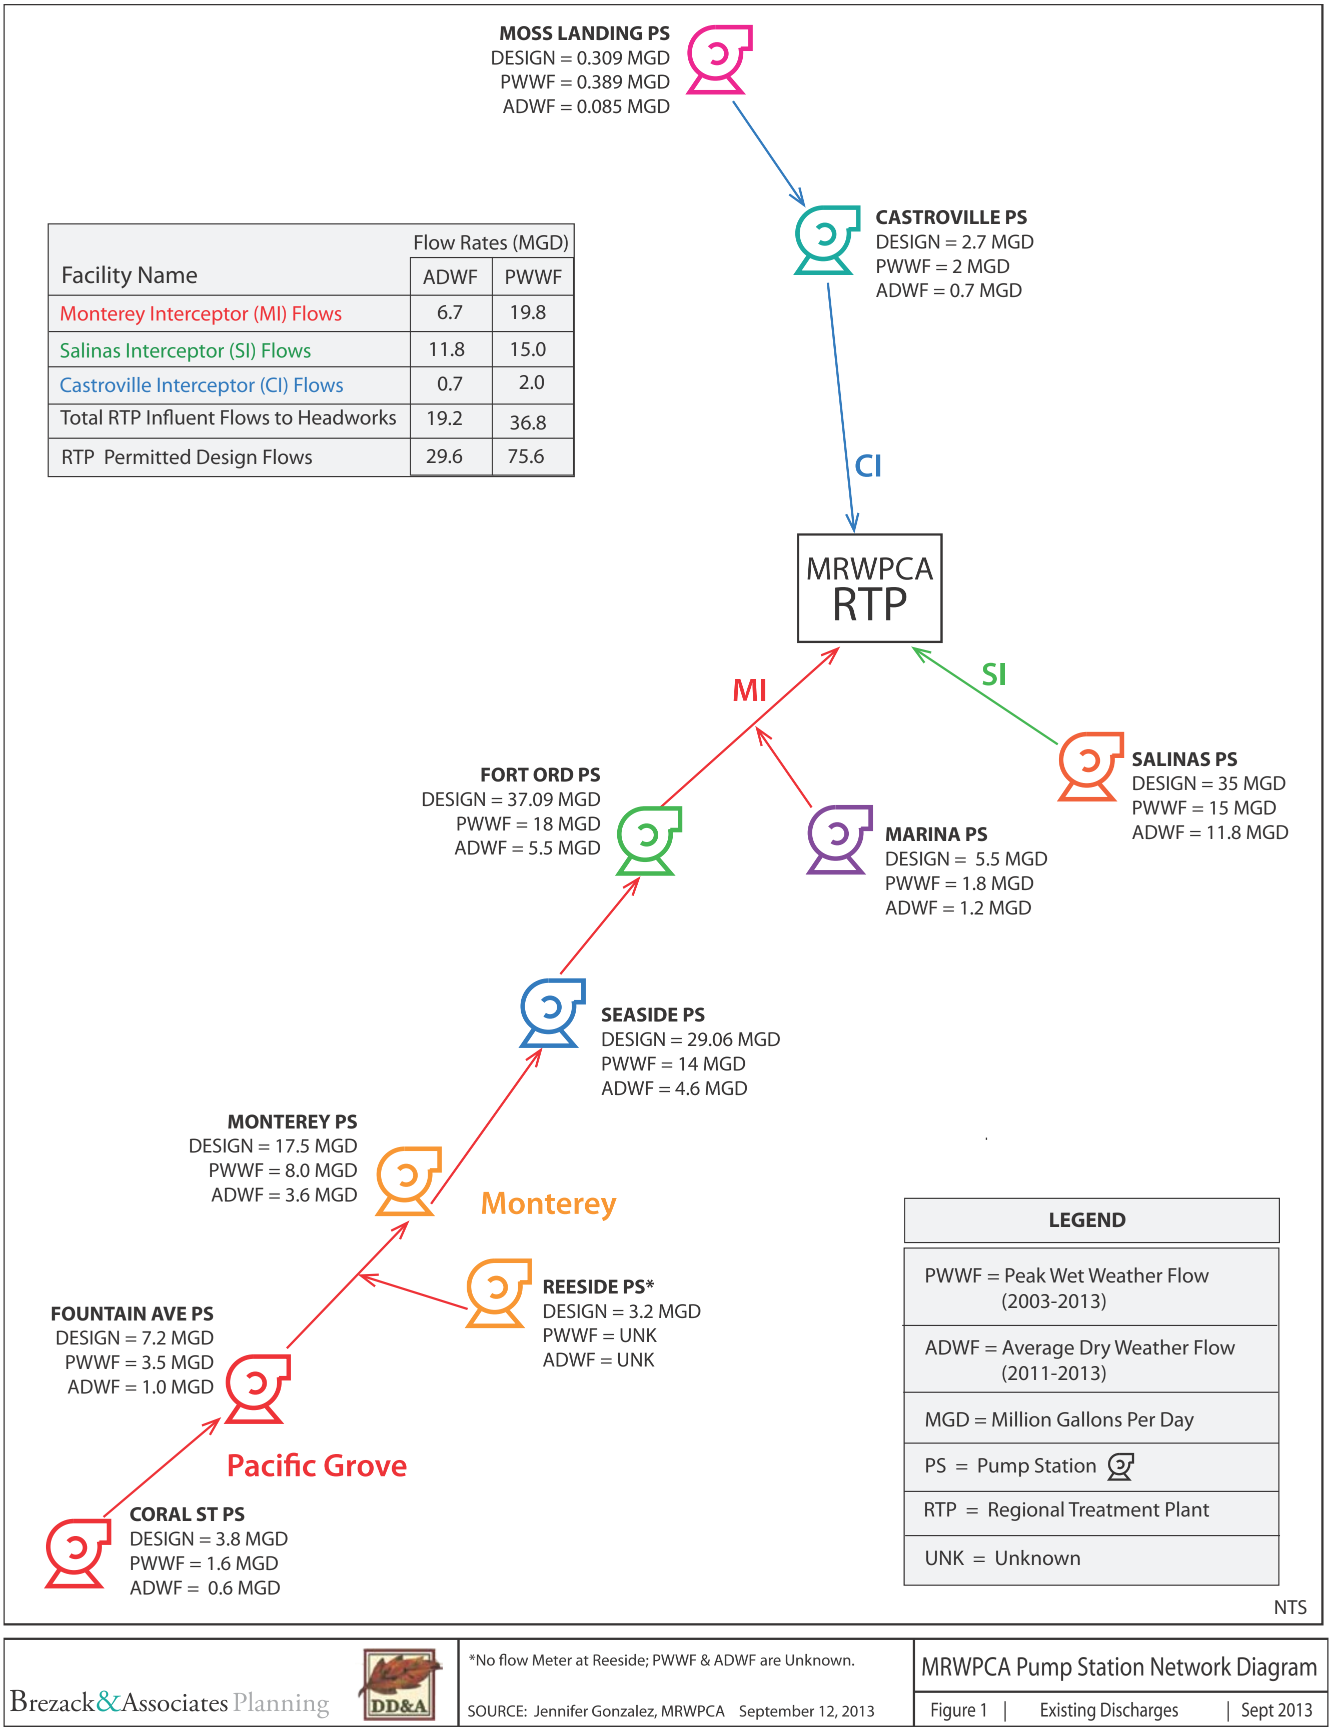

**Figure 2: MRWPCA Pump Station Network Diagram**

# 2 METHODOLOGY

The following wastewater projection methods were considered:

1. Analyzing trends in potable water prices.
2. Correlating economic trends and predictions of water use with assistance from a demographer.
3. Analyzing economic and tourism indicators such as hotel occupancy and ticket sales to the Monterey Bay Aquarium.
4. Using curve-fitting techniques to model future wastewater flow projections based on historical flows.

MRWPCA provided an extensive record of daily wastewater flows from 1999 to 2013 at each of its regional pump stations. This data was used to determine the daily flow of wastewater generated by the communities associated with each pump station, and to aid in choosing a projection method.

The U.S. Census Bureau classifies most of the service areas members as cities. Boronda, Castroville, and Moss Landing are classified as census designated places (CDP). This report uses the word *community* to refer to either designation.

Some communities in the MRWPCA service area lack a designated pump station: Boronda wastewater flows to the Salinas Pump Station, and wastewater from the Cities of Sand City and Del Rey Oaks both flow to the Seaside Pump Station. The Cities of Pacific Grove and Monterey each have two MRWPCA owned pump stations. Only the pump station that collects and pumps the city's total wastewater flow was used in this analysis.

The daily flow record was analyzed as monthly and annual averages to visualize data at different levels of detail. Approximately 47,000 individual data points were used in this investigation, and the few outliers that were identified were reconciled. A memorandum was developed to present the initial analysis and the methods being considered for making flow projections. A workshop meeting was held with MRWPCA staff to review the project and select the method used to complete this analysis. The curve-fitting method was chosen due to the availability of pertinent data.

A spreadsheet model was developed to analyze and project future wastewater flow to the RTP. Trends in historical community populations and wastewater flows produced a range of potential wastewater flow projections. Population data were acquired for each community from the U.S. Census Bureau website. Most cities have a continuous annual record of total population from 2000 to 2012. Data availability for Boronda, Castroville, and Moss Landing was limited to the years 2000 and 2010. Therefore, linear interpolation was used to estimate the populations of Boronda, Castroville, and Moss Landing for the years 2001 through 2009. For simplicity, it was assumed that each community's entire census population contributes to the regional wastewater system. That is, no individual septic or satellite reuse systems were known or evaluated as a part of this work.

The former Fort Ord Military Reservation is not a place recognized by the U.S. Census Bureau for population purposes. Therefore,, data for the populations typically associated with the Ord Community (and therefore the Ford Ord Pump Station) are represented in census counts of the communities with designated jurisdiction, i.e. Seaside, Marina, Del Rey Oaks, and Monterey County.

The population and historical wastewater flow data were used to calculate average flow generated per person in units of gallons per capita per day (GPCD) for the years 2000 through 2012. Trends in population and GPCD in each community were projected forward to the year 2055, and wastewater flow projections were calculated from these trends. Because Seaside, Marina, and Del Rey Oak's population projections account for the population changes attributable to Ord, likewise their flow projections also account for changes in Ord's flow.

A minimum value for GPCD was developed for the purposes of establishing goals for making wastewater flow projections. This minimum GPCD is based in part on the results of an American Water Works Association Research Foundation (AWWARF) residential end use water study (1999). That study found that interior water use on a per capita basis appears to have a theoretical minimum of 69 GPCD. In consideration of the aggressive water conservation measures already in use in many parts of the MRWPCA service area, and the regional value of water, this report adopted a lower minimum value of 59 GPCD. Projections for wastewater flow to the RTP were calculated as summations of community wastewater projections.

# 3 RESULTS

## 3.1 Analysis of Historical Wastewater Flow Data

Average annual wastewater flows to the RTP for years 1999 through 2013 are shown in Figure 3. Wastewater flows to the RTP have been steadily decreasing since 2002. The latest year of record shows the average annual wastewater flow of 17.8 mgd. Relative contributions of each pump station to the RTP changed between 1999 and 2013. Figure 4 and Figure 5 are pie charts representing these relative changes. Noticeably, the Salinas Pump Station contributed the majority of flow, and it increased its relative contribution by 9% for the years of record. The next largest contributor was the Monterey Pump Station, but its relative contribution decreased by 7% for the years on record. Charts presenting individual pump station wastewater flows from 1999 to 2013 are provided in Appendix A.

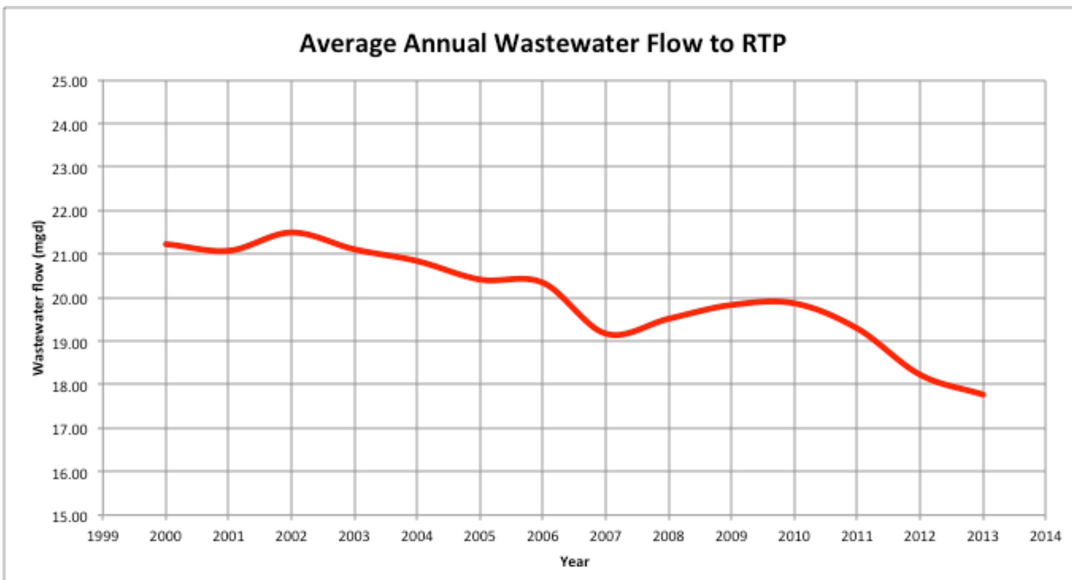

**Figure 3: Average Annual Wastewater Flow to RTP**

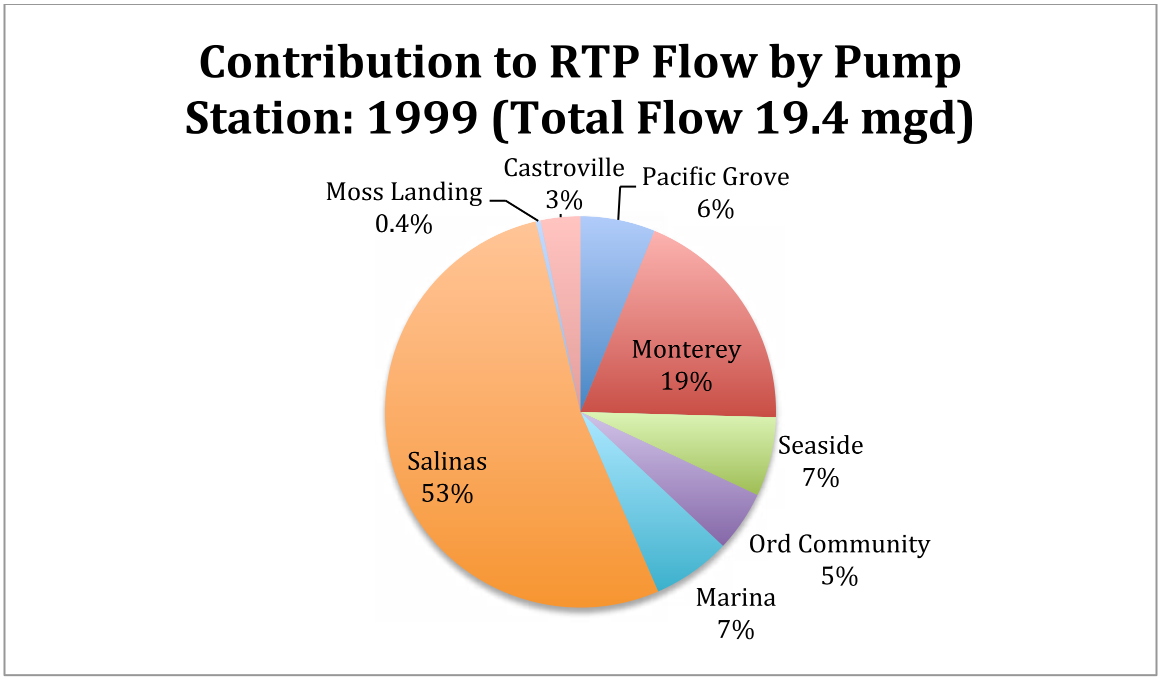

Figure 4: Contribution to RTP Flow by Pump Station: 1999 (Total Flow 19.4 mgd)

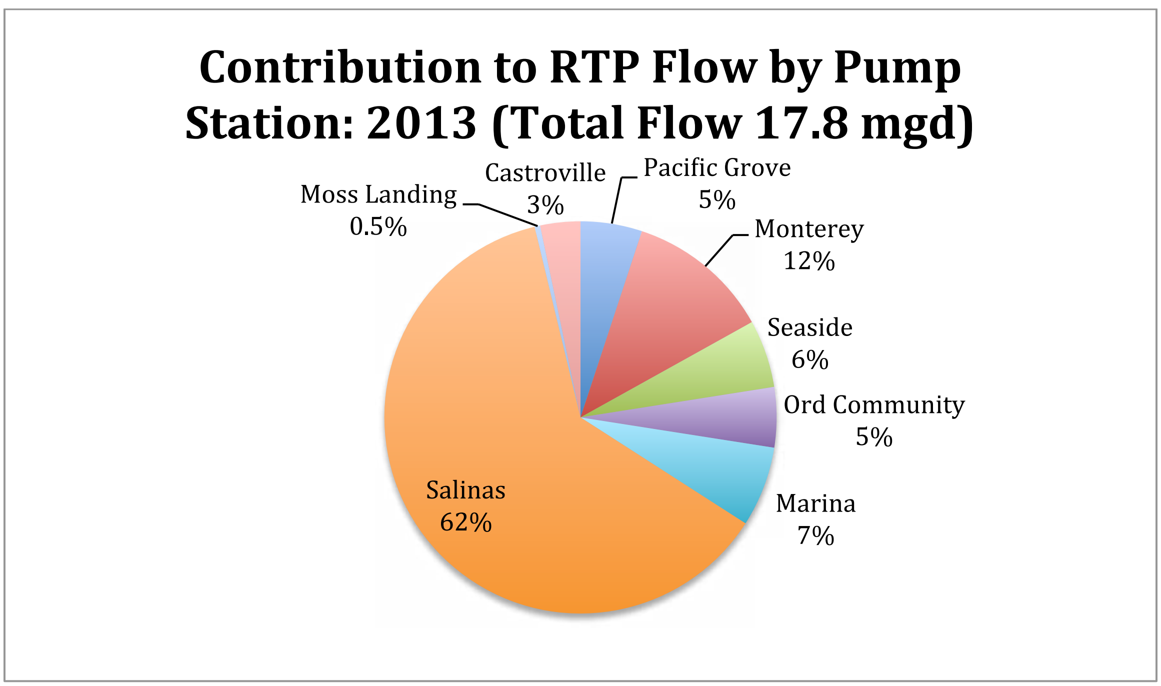

Figure 5: Contribution to RTP Flow by Pump Station: 2013 (Total Flow 17.8 mgd)

### 3.1.1 Statistical Validity of Flow Data

A linear regression analysis performed on flow data at the RTP shows a poor fit and large degree of uncertainty for making flow projections (Figure 6). Population data and GPCD were analyzed to determine whether better flow projections could be calculated.

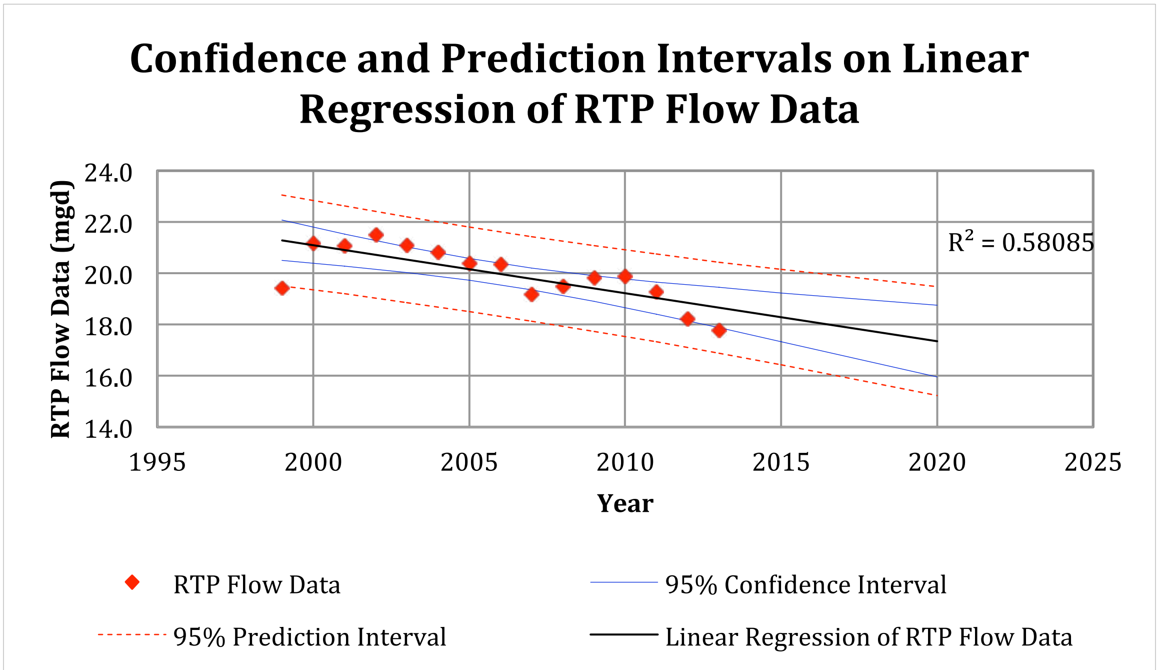

**Figure 6: Confidence and Prediction Intervals on Linear Regression of RTP Flow Data**

## 3.2 Analysis of Census Population Data

Census population data for the total RTP service area for years 2000 through 2012 are plotted in Figure 7. A 2.3% decrease in population from 254,882 to 249,014 is shown between 2001 and 2005. Population increased after 2005. The 2012 estimated MRWPCA service area population is 263,433.

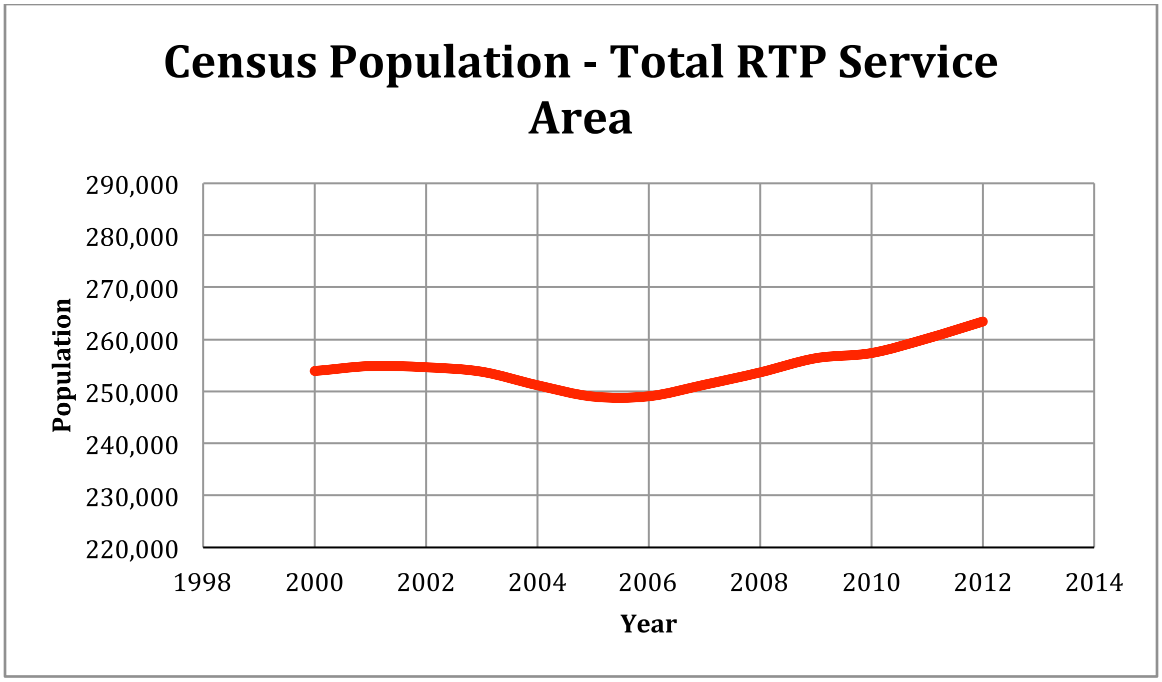

**Figure 7: Census Population – Total RTP Service Area**

### 3.2.1 Statistical Validation of Population Data

Linear and exponential regressions behave similarly given short time frames and steady growth, so for efficiency in analysis, only linear regressions were used to determine confidence intervals.

The decline in population seen between 2000 and 2005 poses a challenge for applying regression analysis to the data. Typical demographic models of population projections fit linear or exponential curves to historical population data[1]. When unusually large and long periods of population decline are used as inputs to the regression, the resulting trend line may not closely align with the most recent group of data points, and confidence and prediction intervals show a large degree of uncertainty. Such was the case of the regression analysis performed on population data from 2000-2012; the resulting regression line shows a poor fit, a larger degree of uncertainty and a much slower trend in growth than what is suggested by the six most recent years on the record. Using only data

[1] Alan Walter Steiss. Population Estimates and Projections. *Local Government Finance: Capital Facilities Planning and Debt Administration*. http://www-personal.umich.edu/~steiss/page55.html

O'Neill, Brian C. et al. A Guide to Global Population Projections. *Demographic Research,* Vol 4, Article 8, Pages 203-288, Published 13 June 2001 www. http://www.demographic-research.org/volumes/vol4/8/4-8.pdf

from 2006 to 2012 produces a trend line with a much better fit and a very small confidence interval.

Both of the above results are useful for making population projections. By their nature, population projections contain a high degree of uncertainty, and it is not appropriate to use confidence intervals to measure uncertainty in long-range projections. Typical demographic methods attempt to capture this uncertainty by producing "high" and "low" projections, that represent extreme scenarios, and an estimate of future value is expected to occur between these curves[2]. In this case, the slow growth trends produced by using the full range of data available from 2000 to 2012 will serve as the "low" projection for each community, and the faster growth trends produced using only the years 2006 through 2012 will serve to create the "high" projection.

Figures 8 and 9 present the statistical confidence intervals of the population trends.

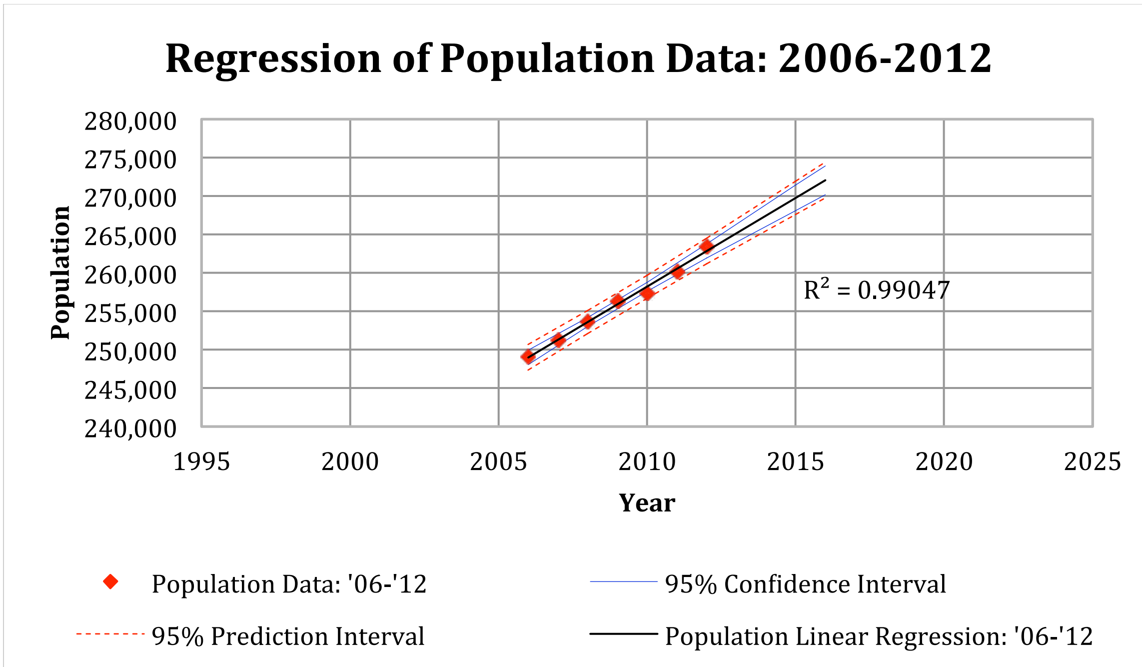

**Figure 9: Confidence and Prediction Intervals on Linear Regression of Population Data: 2006-2012**

## 3.3 Calculation of Historical GPCD

Average wastewater GPCD for the total RTP service area for years 2000 through 2012 were calculated using the historical wastewater flow and population data, as presented in Figure 10. Wastewater generation has trended downward from a 2002 maximum of 84.4 GPCD to a year 2012 minimum of 69.2 GPCD.

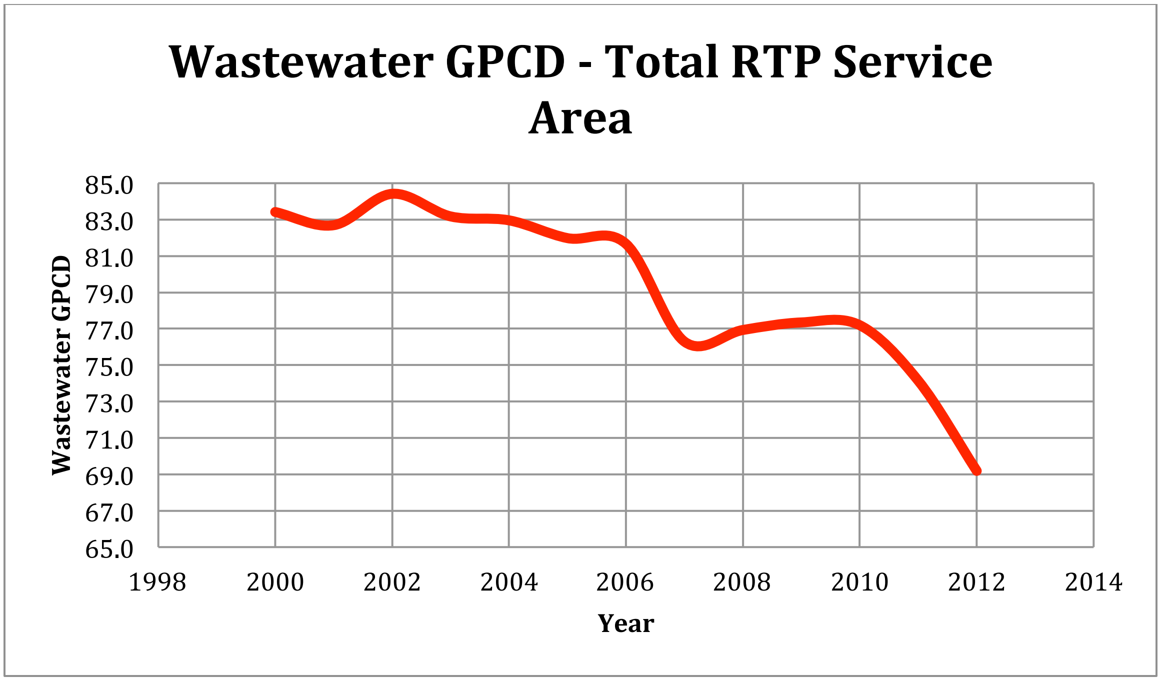

Figure 10: Wastewater GPCD – Total RTP Service Area

#### 3.3.1 Statistical Validation of GPCD

Historical GPCD was calculated from population and flow data, so its variation, goodness of fit in a linear regression, and confidence interval are dependent upon these measured quantities. However, the regression analysis does show that GPCD is linearly correlated with time, useful as an input variable for RTP flow projections (Figure 11).

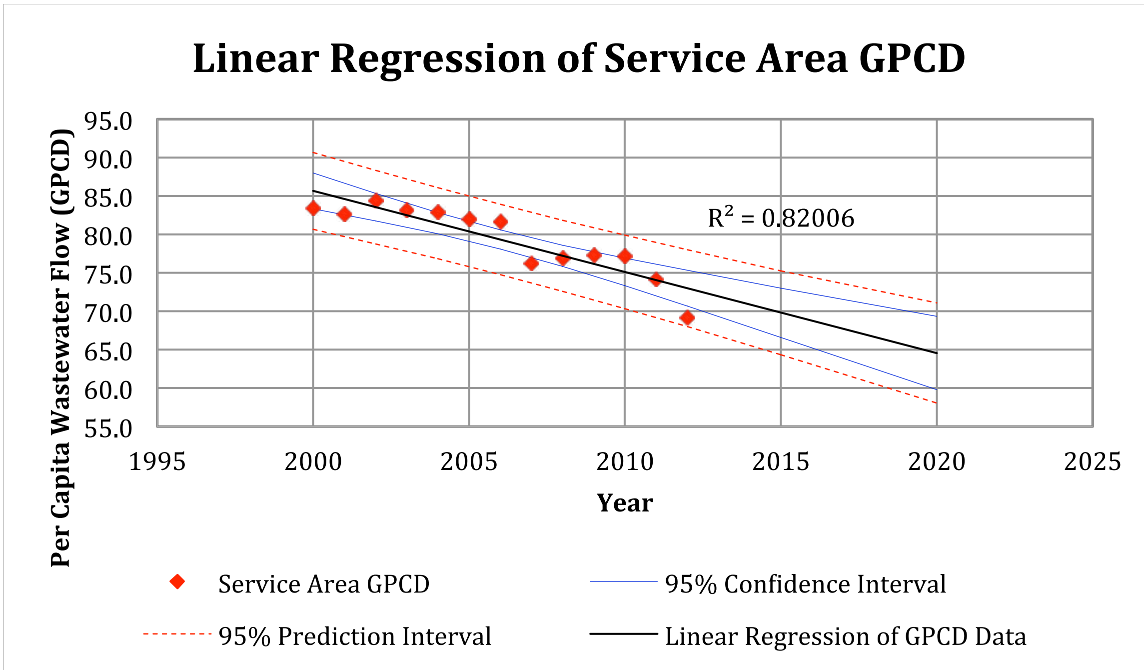

**Figure 11: Confidence and Prediction Intervals on Linear Regression of Historical Service Area GPCD**

## 3.4 RTP Wastewater Flow Projections

MRWPCA service area populations were projected to the year 2055 using the four trends described in Table 1. Linear trends were applied for their simplicity, and exponential trends were applied for their predictions of more rapid growth under ideal conditions. Using the full set of data from 2000 to 2012 provides the most data points for input, while using only 2006 to 2012 data helps attenuate the effects of population decreases between 2000 and 2005. Table 1 shows the percent increase in 2055 population compared to the most current estimates in 2012. Resulting population projections to the RTP are shown in Figure 12.

GPCD projections are made using a phased method. Starting from the present day, GPCD is projected using Trend 1, because regression analysis of historical GPCD showed that a linear trend is appropriate. GPCD cannot realistically fall below zero, so a minimum value is chosen. When the downward linear trend in GPCD meets the minimum value, it is assumed that all future values of GPCD remain constant at this minimum. A report by AWWARF sets an expected value of 69.0 GPCD. Because of strict conservation in the MRWPCA service area, this report chooses 59.0 GPCD as the minimum value.

**Table 1: Description of Population Trend Analysis Methods Used to Produce Range of Wastewater Flow Projections**

| Legend Entry | Description | % Pop. Increase |
|---|---|---|
| Trend 1 | A linear curve is fitted to data from year 2000 to 2012 | 8% |
| Trend 2 | A linear curve is fitted to data from year 2006 to 2012 | 30% |
| Trend 3 | An exponential curve is fitted to data from year 2000 to 2012 | 10% |
| Trend 4 | An exponential curve is fitted to data from year 2006 to 2012 | 48% |

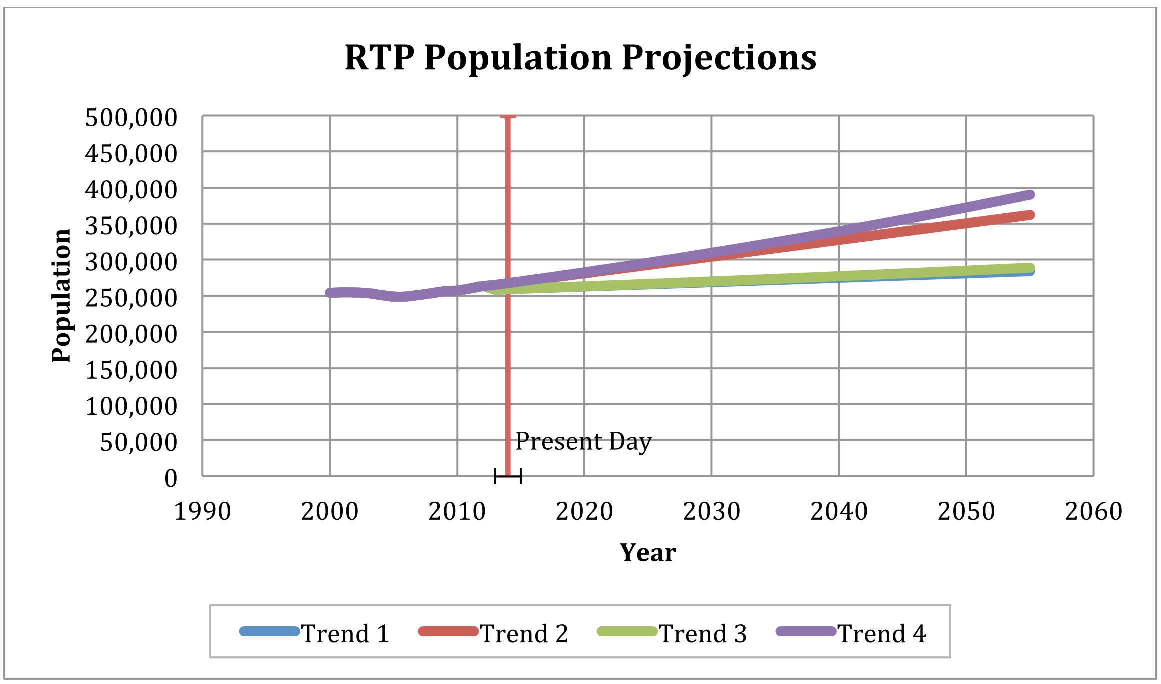

**Figure 12: RTP Service Area Population Projections**

Projections of per capita flow for the total service area is presented in Figure 13. A linear curve was applied to per capita flow data from year 2000 to 2012 and projected forward in time. GPCD values were constrained to the minimum value of 59.0 GPCD.

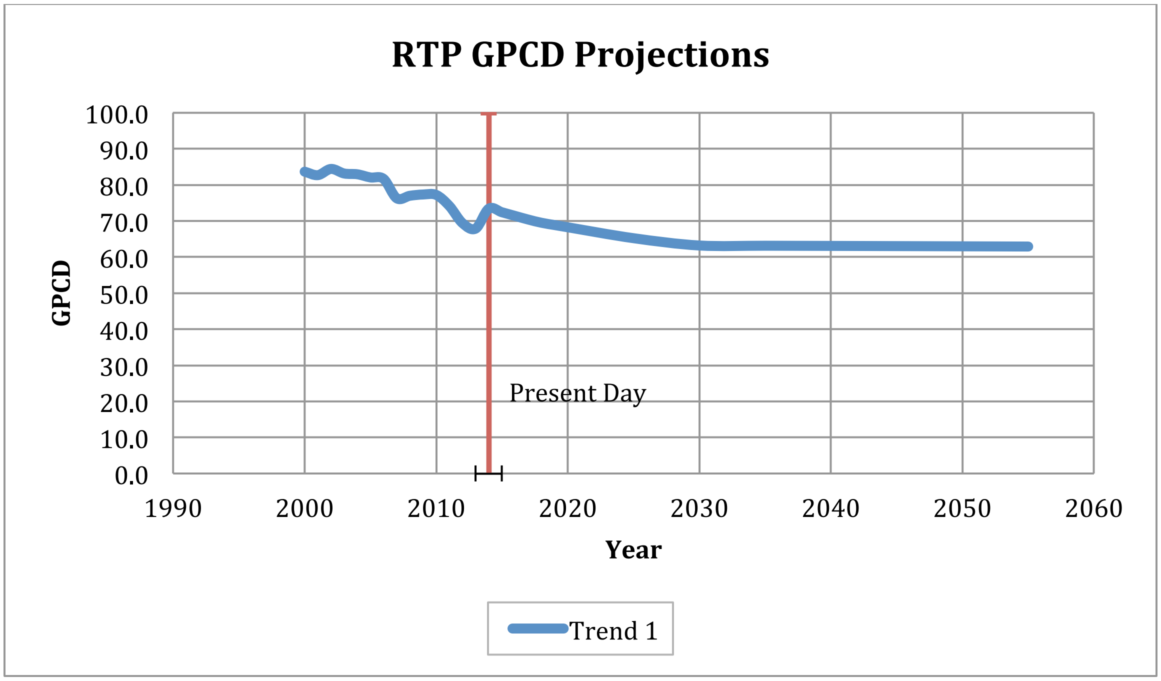

**Figure 13: Average Service Area GPCD Projection**

The set of population and GPCD projections was used to calculate four wastewater flow projections at the RTP, and the results are shown in Figure 14. Lines showing the RTP design capacity and an estimate of build-out wastewater flow (EMC Planning Group, 2013) are shown for reference. Flow to the RTP is projected to decrease until approximately the year 2030, as per capita wastewater flow decreases toward 59.0 GPCD. A resulting estimate of RTP flow for year 2030 is a range between 17.1 and 19.5 mgd. Once GPCD reaches its minimum value, the influence of projected population growth causes projected flow to increase.

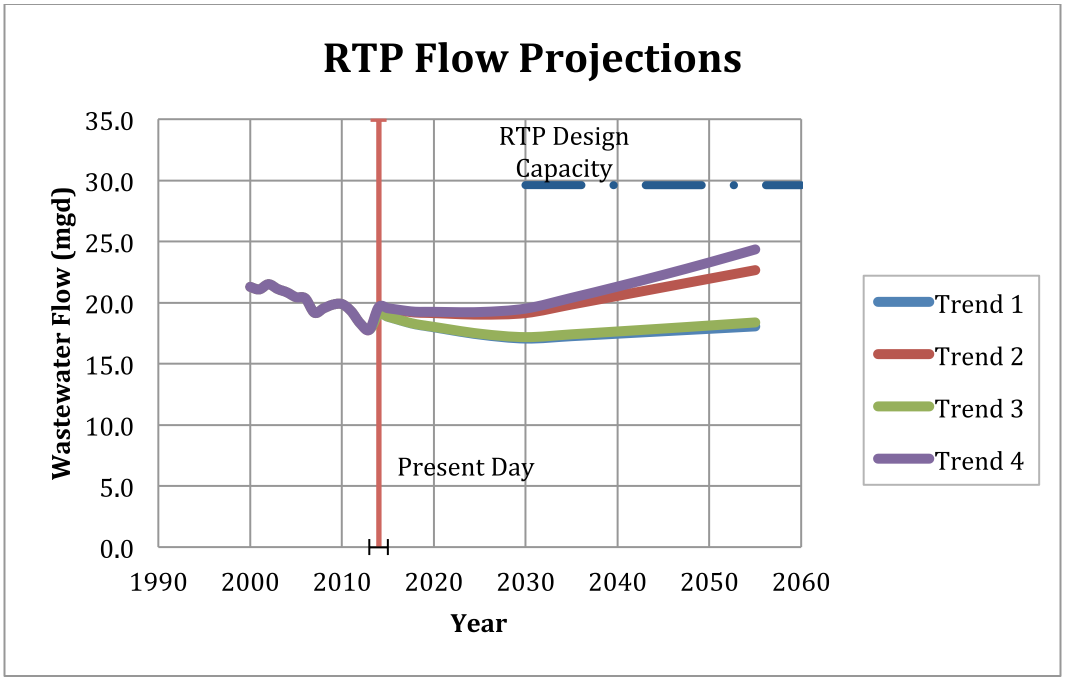

**Figure 14: RTP Wastewater Flow Projections**

Table 2 tabulates the "low" and "high" projections of wastewater flow in 2055 for each community and at the RTP. These represent extreme conditions, and it is expected that the true value will lie between these values.

**Table 2: 2055 Projections of "Low" and "High" Flow Scenarios**

| Pump Station | Low Flow (mgd) | High Flow (mgd) |
|---|---|---|
| **Pacific Grove** | 0.8 | 1.2 |
| **Monterey** | 1.4 | 2.3 |
| **Seaside** | 2.3 | 3.1 |
| **Ord*** | 0.9* | 0.9* |
| **Marina** | 1.1 | 1.6 |
| **Salinas** | 10.9 | 14.6 |
| **Moss Landing** | 0.00 | 0.04 |
| **Castroville** | 0.7 | 0.7 |
| **Total RTP** | 18.1 | 24.3 |

* Projected differences in flow at Ord from the 2013 baseline of 0.9 mgd are included in the flow projections of its surrounding communities, as discussed in the methodology section. The baseline 0.9 mgd is shown here to allow the summation of community flows to equal RTP flow.

THIS PAGE INTENTIONALLY BLANK

# 4 CONCLUSION

Wastewater flows to the RTP from the MRWPCA service area have been decreasing for the past several years. It is projected that flows will continue to decrease until approximately the year 2030, when per capita flows are projected to reach a minimum and flows at the RTP may range between 17.1 and 19.2 mgd. Based on the “high” and “low” projections of population growth and the establishment of a basement GPCD of 59.0, flows are projected to increase after 2030 and may range between 22.7 and 24.3 mgd by the year 2055, i.e. 77% to 82% of RTP design capacity. Other choices in projection methodology and assumptions may produce varying results.

PAGE INTENTIONALLY LEFT BLANK

# 5 RECOMMENDATIONS

The following recommendations are made to improve the accuracy of the wastewater flow projections to the RTP and from each of the MRWPCA service area communities:

1. Update the wastewater flow projection model as new population and flow data becomes available.
2. Use a land use GIS to determine precisely differences in the sewersheds throughout the MRWPCA service area, and delineate the sewershed contributing wastewater flow to each pump station. Review and revise the sewersheds to resolve population data defined by the U.S. Census Bureau.
3. Conduct wastewater flow monitoring and acquire potable water consumption data at Seaside and Moss Landing to validate current wastewater flow data and correct historical flow data.
4. Conduct wastewater flow monitoring for non-residential land uses to verify large connections that may be affecting the wastewater GPCD values. This would include each of the military connections and the large commercial connections.
5. Incorporate the recommendations of a demographer that is familiar with the regional economic constraints and opportunities to validate service area population projections and methodologies.
6. Perform a study of the Fort Ord Pump Station, to determine the portions of Ord's surrounding communities that have sewers linked to the pump station. This will allow for the projection of population growth, GPCD decline, and wastewater flow in the Ord region, which currently goes unrecognized by the Census Bureau.

# APPENDIX L – INSTRUCTIONS FOR ADJUSTING THE MODEL

# Adjusting the Projections Model

The MRWPCA wastewater flow projections spreadsheet model is contained within one Excel 2011 spreadsheet file. The file is separated into multiple worksheets that are viewed by clicking on the named tabs located at the bottom of the open file's window. The model was developed so that new population and flow data may be added and minimum GPCD constraints changed. Changes to the model can be made within the 9 community model worksheets. The community model worksheets are:

- Pacific Grove Model
- Monterey Model
- Seaside Model (includes Del Rey Oaks and Sand City)
- Marina Model
- Salinas Model (includes Boronda)
- Moss Landing Model
- Castroville Model
- RTP Model
- RTP Independent Model

The other worksheets are for reference and calculation purposes only and should not be modified.

The following sections describe the adjustable model features.

## Change Minimum Assumed GPCD

The model accounts for assumptions that per capita wastewater flow is always greater than or equal to a selected baseline value. The baseline value is adjustable by the user. The current model uses 59.0 GPCD as the default assumed minimum baseline value. To test a different minimum assumed GPCD for any community, type the desired number into the box labeled "Min GPCD" at the top of a community model tab. Projected GPCD values will only decrease to values greater than or equal to this minimum value.

| Community | Pacific Grove |
|---|---|
| Min GPCD | 59.0 |

| | | pulation | | | | GPCD | Wastewater Flow | | | |
|---|---|---|---|---|---|---|---|---|---|---|

## Input New Population and Flow Data

Green shaded cells in the community model tabs contain historical data, while unshaded cells contain projected values. To update the community models with the latest actual population data, type the new data into the first year of unshaded projections. Because four different population projections are made to account for a range of possible scenarios, there are four columns of population data that need to be updated. For example, if the U.S. Census publishes a 2013 population estimate of 15,600 for the city of Pacific Grove, type 15,600 into each of the four population columns corresponding to the year 2013.

Use the same method to input the latest actual wastewater flow data.

After a row is updated with actual data for both population and wastewater flow, update the GPCD cell in the same row by copying the green shaded GPCD cell from the row above, right clicking the unshaded cell to be updated, select Paste Special, then choose Formulas from the pop-up menu.

As a visual aid, shade the new cells containing actual data green: select the cells, right click, and choose Format Cells from the pop-up menu. From the window that appears, select the fill tab, and choose light green to shade the cells to signify that they contain data and not projections.

Update population projections by double clicking the population projection cell under the row that was just updated. The data used as inputs to this cell should appear as colored rectangles on the spreadsheet. Click and drag the bottom corners of the rectangles covering the input population data and input years so that the rectangle enlarges to also cover the new population data value entered and its corresponding year. Press Enter. Right click the cell, select copy, then highlight all rows of unshaded projections within that column, taking care not to highlight any rows of actual data. Right click, select Paste Special, then choose Formulas from the pop-up menu. The formulas used to calculate population projections should update. Repeat the steps from this paragraph for the remaining columns of population projections.

Once the population projections are updated by following these steps, the wastewater flow projections automatically update.

## Adjust "Present Day" on Graphs

The red vertical bars in the projection graphs are visual aids that can be individually adjusted to match the current year. To do this, right click anywhere on the graph and choose "Select Data." A pop-up menu will open. From the list of data series on the left, scroll down and click "Present Day." Change the "X–value" on the right by typing in an equal sign, a curly brace, the current year, and a closing curly brace.

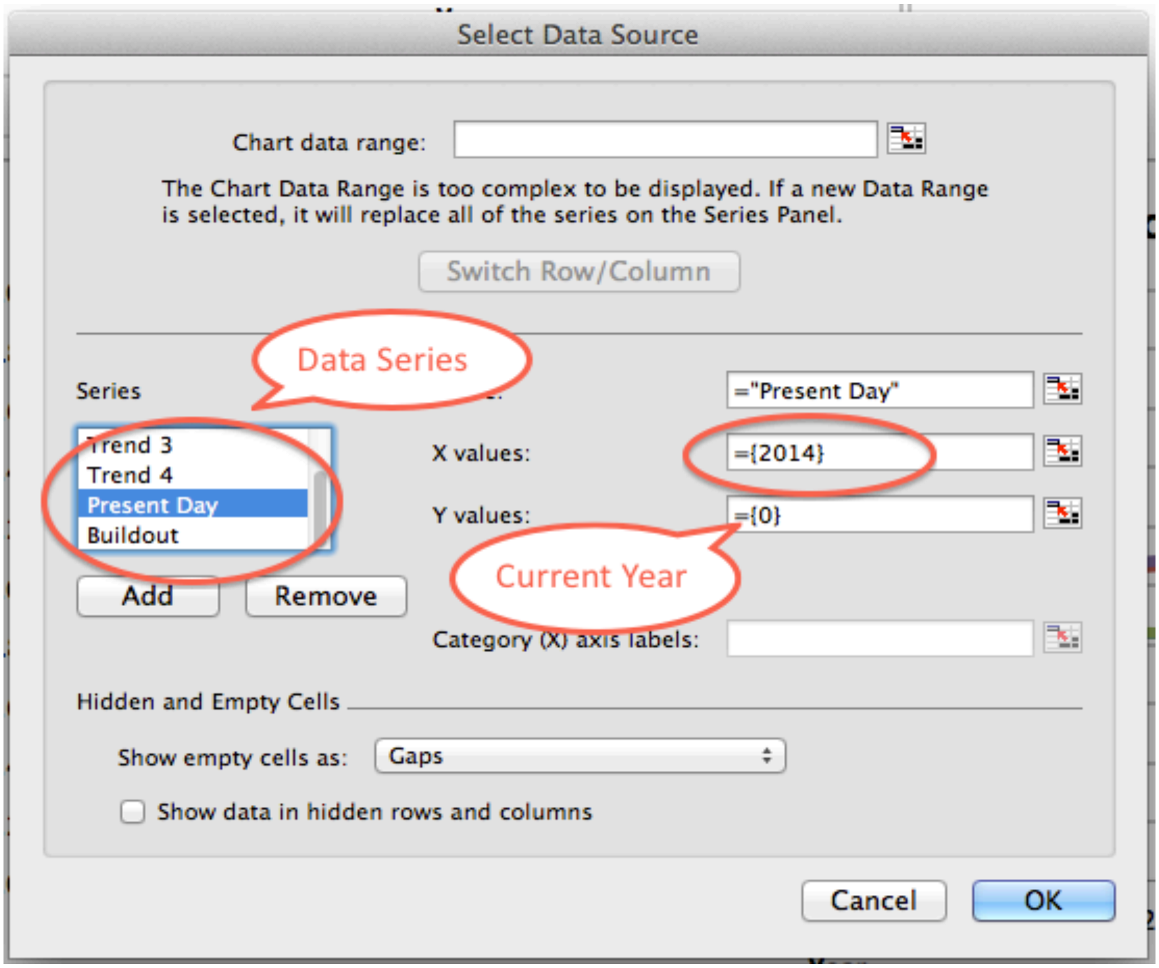

Figure 30: Input “Present Day” on Graphs

## Independent RTP Projections

Changes made to population and wastewater flow projections in individual community spreadsheets are calculated to accumulate in the RTP projection results, presented in the worksheet “RTP Model”. That is, RTP wastewater flow projections are made from cumulative results at the community level.

To test changes in population and wastewater flow projections or GPCD constraints at the RTP independently from the behavior of its communities, use the “RTP Independent Model” spreadsheet tab in the same manner as other community tabs.  This worksheet relies on flow data directly from the RTP and is not data calculated from the regional pump stations.

## TABLE Y-1

**MPWSP WITH 6.4 MGD DESALINATION PLANT (ALSO KNOWN AS CALAM FACILITIES OF THE MPWSP VARIANT)**

(Source: ESA, March 21, 2015)

| Facility | Description | Purpose |
|---|---|---|
| **Seawater Intake System** | | |
| Subsurface Slant Wells | • Seven slant wells (*vs. ten slant wells under the proposed project*) extending offshore beneath the Monterey Bay (the conversion of an existing test slant well into a permanent well plus six new wells), with up to five wells (*vs. eight wells under the proposed project*) operating at any given time and two wells maintained on standby<br>• The slant wells would be grouped into two well clusters (*vs. three well clusters under the proposed project*), one with four wells and the other with three wells<br>• Each slant well would be equipped with a 2,200-gallon-per-minute (gpm) submersible well pump<br>• Each well would be approximately 700 to 800 feet long and extend offshore to a depth of approximately 200 to 220 feet below mean sea level (msl)<br>• The wells would be screened in the Dune Sands Aquifer and the 180-Foot-Equivalent Aquifer of the Salinas Valley Groundwater Basin | These wells would draw approximately 15 mgd of seawater (*vs. 24 mgd under the proposed project*) from beneath the ocean floor for use as source water for the MPWSP Desalination Plant. |
| Source Water Pipeline | • 2.7-mile-long 42-inch-diameter pipeline | This pipeline would convey the combined source water from the slant well clusters to the MPWSP Desalination Plant. |
| **Desalination Facilities** | | |
| Pretreatment System | • Pressure filters or multimedia gravity filters would be housed within a 6,000-square-foot pretreatment building<br>• Two 300,000-gallon backwash supply and filtered water equalization tanks<br>• Two 0.25-acre, 6-foot-deep lined backwash settling basins with decanting system | The pretreatment system would treat source water to remove suspended and dissolved contaminants that could damage the RO system, and thus increase the efficiency and lifespan of the RO system. |
| Reverse Osmosis (RO) System | • Dual-pass RO system consisting of four active modules and one standby module, with each module producing 1.6 mgd of "permeate" (the purified water produced through the RO membrane)<br>• UV disinfection system (if required)<br>• The RO and post-treatment systems and chemical storage tanks would be housed within a 30,000-square-foot process and electrical building | The RO system would remove salts and other minerals from pretreated source water. If required by the California Department of Public Health, the UV Disinfection system would provide additional primary disinfection |
| Post-treatment System | • Chemical feedlines and injection stations (for carbon dioxide, lime, sodium hydroxide, phosphate-based corrosion inhibitor, and sodium hypochlorite) | The post-treatment system would adjust the hardness, pH, and alkalinity of the desalinated product water and disinfect the water in accordance with drinking water requirements. |
| Chemical Storage | • Chemical storage tanks with secondary containment<br>• Sumps and sump pumps | This facility would provide for chemical storage. The capacity of the chemical storage tanks would range from less than 5,000 gallons to 20,000 gallons, depending on the treatment chemical. |
| Administrative Building | • 4,000- to 6,000-square-foot building | This building would house restrooms, locker rooms, break rooms, conference rooms, electrical controls, laboratory facilities, equipment storage and maintenance, and electrical service equipment. |
| **Brine Storage and Disposal Facilities** | | |
| Brine Storage and Disposal | • 3-million-gallon brine storage basin<br>• 1-mile-long, 30-inch-diameter Brine Discharge Pipeline | Approximately 8.99 mgd of brine (*vs. 13.98 mgd of brine under the proposed project*) would be generated by the RO process. Brine concentrate produced during the RO process would be conveyed to the brine storage basin located at the MPWSP Desalination Plant. The Brine Discharge Pipeline would convey decanted effluent from the pretreatment filtration backwash cycle and RO concentrate produced by the RO system to an existing ocean outfall. |
| MRWPCA Ocean Outfall Pipeline and Diffuser (existing) | • 2.3-mile long, 60-inch-diameter pipe (onshore portion)<br>• 2.1-mile-long, 60-inch-diameter pipe<br>• 1,100-foot-long diffuser with 172 ports (120 ports are open and 52 are closed), each 2 inches in diameter and spaced 8 feet apart | Brine and pretreatment backwash effluent from the desalination plant would be conveyed to the existing ocean outfall pipeline. The outfall would terminate at a diffuser located offshore that would discharge the concentrate to Monterey Bay. |
| **Desalinated Water Conveyance and Storage Facilities** | | |
| Clearwells (Water Storage Tanks) and Clearwell Pump Station | • 6.4-mgd, 120-horsepower pump<br>• Two 85-foot-diameter, 750,000-gallon aboveground storage tanks (providing a total combined storage volume of 1.5 million gallons) | The clearwell pump station would pump water from the post-treatment process to the clearwells. The clearwells would serve as holding tanks from which water would be pumped to either the CalAm water system or the existing Castroville Seawater Intrusion Project (CSIP) pond. |
| Desalinated Water Pump Station | • 6.4-mgd, 800-horsepower pump to pump water through the Desalinated Water Pipeline to the CalAm water system<br>• 1.4-mgd, 20-horsepower pump to pump water through the Salinas Valley Return Pipeline to the CSIP pond | This facility would pump desalinated product water from the MPWSP Desalination Plant to the CalAm water system and existing CSIP pond. |
| Salinas Valley Return Pipeline | • 1.2-mile-long, 12-inch-diameter pipeline | This pipeline would convey desalinated product water from the MPWSP Desalination Plant to the CSIP pond for subsequent delivery to agricultural users in the Salinas Valley. |
| Desalinated Water Pipeline | • 3.25-mile-long, 36-inch-diameter pipeline | This pipeline would convey desalinated product water from the clearwells at the MPWSP Desalination Plant to the Transmission Main at Reservation Road. |
| Transmission Main | • 6-mile-long, 36-inch-diameter force main | This pipeline would convey desalinated product water between the Desalinated Water Pipeline at Reservation Road to the Monterey Pipeline and Transfer Pipeline at the intersection of Del Monte Boulevard/La Salle Avenue. |
| Transfer Pipeline | • 2.4-mile-long, 36-inch-diameter pipeline (could be operated in both directions) | This pipeline would convey desalinated product water or water that is extracted from the ASR injection/extraction wells (including GWR product water) to the Terminal Reservoir for storage; water extracted from ASR directly to the CalAm distribution system; and water stored in Terminal Reservoir to the CalAm distribution system. |
| Monterey Pipeline | • 5.4-mile-long, 36-inch-diameter pipeline (could be operated in both directions) | This pipeline would convey CalAm water supplies (including desalinated product water, ASR product water, and GWR product water) between Seaside and the Monterey Peninsula. |

## TABLE Y-1

**MPWSP WITH 6.4 MGD DESALINATION PLANT (ALSO KNOWN AS CALAM FACILITIES OF THE MPWSP VARIANT)**

(Source: ESA, March 21, 2015)

| Facility | Description | Purpose |
|---|---|---|
| Interconnection Improvements for State Route 68 Satellite Systems<br>a) Ryan Ranch–Bishop Interconnection<br>b) Main System–Hidden Hills Interconnection | a) 1.1-mile-long, 8-inch-diameter pipeline<br>b) 1,200-foot-long, 6-inch-diameter pipeline | These interconnection pipelines and associated improvements would allow MPWSP supplies to be conveyed to the Ryan Ranch, Bishop, and Hidden Hills water systems. |
| Terminal Reservoir | • Two 3-million-gallon storage tanks | These tanks would store desalinated product water and ASR product water. |
| Valley Greens Pump Station | • 3-mgd, 100-horsepower pump station | This 600-square-foot facility would provide the additional water pressure needed to pump water through the existing Segunda Pipeline into Segunda Reservoir. |
| **ASR System** | | |
| Six ASR Injection/Extraction Wells (four existing wells and two proposed):<br>a) ASR-1, ASR-2, ASR-3, and ASR-4 Wells (existing)<br>b) ASR-5 and ASR-6 Wells (proposed) | • Two proposed 1,000-foot-deep injection/extraction wells (ASR-5 and ASR-6 Wells) with a combined injection capacity of 2.2 mgd and extraction capacity of 4.3 mgd<br>• Four existing injection/extraction wells (Phase I and II wells) | The existing and proposed ASR injection/extraction wells would be used to inject Carmel River supplies and desalinated product water into the Seaside Groundwater Basin for storage. During periods of peak demand, the wells would be used to extract water that is stored in the Seaside Groundwater Basin (including Carmel River supplies, desalinated product water, and GWR product water) for subsequent delivery to customers. |
| ASR Pump Station | • 8.4-mgd, 300-horsepower pump station | This pump station would be used to pump water to and from the ASR injection/extraction wells through existing and proposed pipelines. |
| ASR Conveyance Pipelines | • Two parallel 0.9-mile-long, 30-inch-diameter pipelines | One of these pipelines would be used to convey water from existing conveyance facilities at the corner of Coe Avenue and General Jim Moore Boulevard to the new ASR-5 and ASR-6 Wells for injection; the other pipeline would be used to convey extracted ASR supplies to the same existing facilities. |
| ASR Pump-to-Waste System | • 0.9-mile-long, 16-inch-diameter pipeline<br>• 4,800-square-foot, 12-foot-deep settling basin | The ASR Pump-to-Waste System would flush sediment and other suspended solids out of the two proposed ASR injection/extraction wells and convey it to a new settling basin (the proposed ASR Settling Basin) at the same site, or to the existing settling basin for the ASR-1 and ASR-2 Wells located approximately 2 miles to the south. The ASR Pump-to-Waste Pipeline would connect to existing pump-to-waste pipelines located at the intersection of General Jim Moore Boulevard and Coe Avenue. |

**PROPOSED GWR PROJECT WITHOUT CALAM DISTRIBUTION SYSTEM: MONTEREY AND TRANSFER PIPELINES**

(ALSO KNOWN AS GWR FACILITIES OF THE MPWSP VARIANT)

| Facility | Description | Purpose |
|---|---|---|
| **New Source Water Diversion and Storage Facilities** | | |
| Diversion facilities for Unused Treated Wastewater from MRWPCA Regional Treatment Plant | New diversion structure on the existing secondary effluent pipeline to capture unused secondary-treated effluent. This facility is described as part of the Treatment Facilities at the Regional Treatment Plant | To capture unused secondary-treated effluent and divert it to the proposed AWT Facility. |
| Salinas Pump Station Diversion and Salinas Treatment Facility Storage and Recovery Improvements | Salinas Pump Station Diversion:<br>– Underground junction structure constructed over the existing 48-inch sanitary sewer line, to mix sanitary, agricultural wash waster and stormwater flows. This structure would also receive agricultural wash water and stormwater return flow from the Salinas Treatment Facility's Pond 3.<br>– Modifications to the existing agricultural wash water underground diversion structure and the addition of 42-inch diameter 150-foot long underground pipeline and metering structure.<br>– Underground stormwater diversion structure and underground pipeline between this structure and the existing 33-inch agricultural wash water line.<br>– Underground stormwater diversion structure and underground pipeline to divert to divert stormwater flow to the Salinas Pump Station through an existing 30-inch abandoned pipeline.<br>– Meters, valves, electrical and control systems, and fencing around the diversion structures<br>Salinas Treatment Facility Storage and Recovery Improvements:<br>– Return pump station including valve, mater vault, and two variable frequency drive pumps<br>– 18-inch return pipeline connecting the pump station to the Salinas Diversion site<br>– Pipeline connecting Pond 3 to the new return pump station<br>– Pump station near the lower end of Pond 3<br>– Pipeline to convey treated wastewater from the aeration basin to the pipeline that returns waster from Pond 3 or directly to the return pump station. | Water would be diverted to the existing Salinas Pump Station using a new diversion structure and new short pipelines connecting the existing agricultural wash water pipeline to the existing municipal wastewater system. The agricultural wash water would then mix with the municipal wastewater and be conveyed through the existing 36-inch diameter Salinas interceptor to the Regional Wastewater Treatment Plant.<br>City of Salinas urban runoff and stormwater would be diverted to the Regional Wastewater Treatment Plant rather than discharged to the Salinas River. |
| Reclamation Ditch Diversion at Davis Road | • Diversion structure consisting of a intake structure connecting to a wet well (manhole) via a gravity pipeline<br>• Two submersible pumps installed within the wet well, controlled by variable frequency drives<br>• Valve and meter vaults<br>• Weatherproof cabinet enclosing electrical controls and drives<br>• Two short force main approximate 50 foot long, discharging to an existing manhole on the City of Salinas 54-inch sewer main<br>• Modification to existing sanitary manhole and a short pipeline from the existing manhole to the pump station | To divert and convey source waters from the Reclamation Ditch to the Regional Treatment Plant |
| Tembladero Slough Diversion at Castroville | • Intake structure connecting to a new lift station wet well (manhole) via a gravity pipeline<br>• Modifications to the existing Castroville Pump Station<br>• Two submersible pumps installed within the wet well, controlled by variable frequency drives<br>• Weatherproof cabinet enclosing electrical controls and drives<br>• Short force main approximate 100 foot long discharging to the existing wet well at the MRWPCA Castroville Pump Station<br>• Underground valve vault, isolation valves and flow meter | To divert and convey source waters from the Tembladero Slough to the Regional Treatment Plant. |
| Blanco Drain Diversion Pump Station and Pipeline | • Intake structure connecting to a wet well (manhole) via a gravity pipeline<br>• Two submersible pumps installed within the wet well, controlled by variable frequency drives<br>• Weatherproof cabinet enclosing electrical controls and drives<br>• The pump station would discharge through a18-inch force main and a 30-inch gravity main, running from the pump station to the headworks for the Regional Wastewater Treatment Plant<br>• Underground valve vault, isolation valves and flow meter<br>• Surge tank | To divert and convey source water from the Blanco Drain watershed to the Regional Treatment Plant. |
| Lake El Estero Diversion | Lake El Estero Source Water Diversion System Option 1:<br>– Pumping system consisting of a new column pump installed in the wet well of the existing lake management pump station<br>– Upgrades to the existing electric panel<br>– 30-foot long, 12-inch diameter discharge pipeline<br>Lake El Estero Source Water Diversion System Option 2:<br>– Gravity system consisting headwall and screen intake pipe<br>– 40-foot long, 12-inch diameter discharge pipeline<br>– Isolation valve (controlled and motorized) | Lake El Estero Source Water Diversion System would connect existing facilities and convey the new source water flows to the Regional Treatment Plant. |
| **New Treatment Facilities and Modifications at the MRWPCA Regional Wastewater Treatment Plant** | | |
| Inlet Raw Water Diversion Structure and Pump Station | • Diversion structure installed on an existing secondary effluent pipeline at the Regional Treatment Plan<br>• Influent pump station (subgrade wetwell and pumps) | The diversion structure would divert and convey secondary effluent source water to the proposed Advanced Water Treatment Facility.<br>The influent pump station would accept and equalize the Regional Wastewater Treatment Plant secondary effluent flow. |
| Raw Water Pretreatment | Chloramination<br>– Sodium hypochlorite storage<br>– Chemical feed pumps<br>– Inline injection and mixing system<br>Ozonation<br>– Liquid oxygen storage and vaporizers or onsite oxygen generator<br>– Nitrogen boost system<br>– Ozone generator and power supply unit<br>– Cooling water system<br>– Side-stream injection system<br>– Ozone contactor<br>– Ozone destruct units<br>Biologically active filtration (if required)<br>– Gravity-feed filter basins with approximately 12 feet if granular media, and an underdrain/media support system<br>– Ancillary systems<br>Alkalinity addition system for pH control, backwash water basin, backwash pumps, air compressor and a supply system for an air scour system, air compressor and a supply system for process air, and a wash water basin to facilitate filter backwashing | Before membrane filtration, the secondary effluent would be pretreated using these pre-screening methods in up to three separate subsystems.<br>Chloramines would be used to reduce biofouling of the membrane systems.<br>Ozone treatment would provide a chemical/pathogen destruction barrier and reduce the membrane fouling.<br>Biologically active filtration (if required) would be used downstream of ozone treatment to reduce the concentration of residual organic matter present in the ozone effluent and to reduce the solids loading on the membrane filtration process. |

## TABLE Y-2

**PROPOSED GWR PROJECT WITHOUT CALAM DISTRIBUTION SYSTEM: MONTEREY AND TRANSFER PIPELINES**

(ALSO KNOWN AS GWR FACILITIES OF THE MPWSP VARIANT)

| Facility | Description | Purpose |
|---|---|---|
| Microfiltration/Ultrafiltration Membrane Treatment System | Membrane filtration system<br>– Hollow fiber membrane modules<br>– Valve manifolds to direct the flow of feed, filtrate, cleaning solutions, backwash supply, backwash waste, and compressed air to the corresponding module connecting piping.<br>– Feed pumps | The membrane filtration system would remove suspended and colloidal solids, including bacteria and protozoa through hollow fiber membrane modules. |
| Reverse Osmosis Membrane Treatment System | Individual process trains housing the process membranes in pressure vessels along with connecting piping and valve manifolds for feed, permeate, concentrate, cleaning and flush supplies. | The reverse osmosis process that employs semi-permeable membranes is proposed to remove dissolved salts, inorganic and organic constituents, and pathogens from the membrane filtration treated water. |
| Advanced Oxidation Process System | • Chemical feed to add hydrogen peroxide and reactors housing arrays of ultraviolet lamps along with ballasts to power the ultraviolet system. | The advanced oxidation system would provide a final polishing step for pathogen disinfection and would provide an additional chemical destruction barrier for the reverse osmosis permeate. |
| Post-Treatment System | • Post-treatment stabilization system | Post-treatment stabilization of the product water would prevent corrosion of pipe materials in the product water conveyance system. Stabilization would also be used to reduce the potential for product water to leach minerals and other chemicals from the soils within the Seaside Groundwater Basin upon injection. |
| Advanced Water Treatment Pump Station | • Pump station constructed on a new concrete pad<br>• Split-faced block building approximately 30 feet by 70 feet and up to 25 feet tall.<br>- Pump motors<br>- Discharge piping<br>- Electrical power equipment<br>- HVAC<br>- Instrumentation and control equipment<br>• Electrical supply transformer<br>• Pressurized surge tank<br>• Standby pumping units for pump stations | The Advanced Water Treatment Pump Station would pump the product water into the product water conveyance pipeline. |
| Brine Mixing Facility | • Two cast-in-place concrete vaults on the existing outfall<br>• A cast-in-place concrete mixing structure with a 60-inch static mixer in a fiberglass mixing pipe and air release valve<br>• Pipelines and valves<br>• Flow meters<br>• Sampling port<br>• Two sluice gates<br>• Air release valve<br>• Lab and control building | The Brine Mixing Facility would thoroughly mixed osmosis reject or concentrate water (or brine) to prevent stratification of MRWPCA's ocean outfall that may lead to complicated corrosion potential to the outfall pipe and to optimize the mixing with sea water in the bay. this is also the connection point between the Desalination Brine Discharge Pipelines and the PCA's outfall |
| Power Supply | • Utility service<br>• Transformers<br>• Switchgear | The Advanced Water Treatment Facility power would be supplied through a new PG&E utility connection. |
| Salinas Valley Reclamation Plant Modifications | • Sluice gates<br>• A new pipeline between the existing inlet and outlet structures with the storage pond<br>• Chlorination basin upgrades | Modifications would enable the plant to produce more continuous flows in the winter when demand by the CSIP users decreases to as low as 0.5 mgd. |
| **GWR Product Water Conveyance Facilities** | | |
| RUWAP Alignment (Option 1) or Coastal Alignment (Option 2) | • 24-inch-diameter pipeline<br>• In-line isolation valves on the pipeline approximately every 2,000 feet | Conveys the advanced treated product water from the proposed Advanced Water Treatment Facility to the Seaside Groundwater Basin for injection. The Product Water Conveyance system would be designed to convey a total of up to 3,700 afy of product water to the proposed new injection wells. |
| Booster Pump Station | • 2,100-sqaure foot, up to 25 foot tall booster pump station building<br>• Split-faced block building<br>– Pump motors<br>– Discharge piping<br>– Electrical power equipment<br>– HVAC<br>– Instrumentation and control equipment<br>• Electrical supply transformer<br>• Pressurized surge tank<br>• Standby pumping units for pump stations | The Booster Pump Station would provide adequate pressure to convey the Advanced Water Treatment product water to the proposed new GWR Injection Well Facilities for injection. |
| **GWR Injection Well Facilities** | | |
| Injection Well Clusters | • Four deep injection wells (DIW-1, DIW-2, DIW-3 and DIW-4) with a combined injection capacity of 4.6 mgd. And four vadose zone well (VZW-1, VZW-2, VZW-3, and VZW-4) with a combined injection capacity of 2.88 mgd. Each well cluster would include one of each type of well and the following:<br>– Back flushing pump and motors<br>– Above and below grade injection and back-flush wash pipelines<br>– Values and flow meters<br>– Small building (approximately 16 feet by 24 feet) for electrical and control equipment<br>• Wells would be constructed in close proximity to each other to share electrical, motor control, pumps, and site building pad infrastructure. | The proposed injection wells would be used to inject product water into the Seaside Groundwater Basin. |
| Backflush Facilities | • 2,000 gpm back-flush well pump, flow meter, electrical cabinet and 400 hp motor attached to the injection well<br>• Pipeline to convey the back-flushed water to the percolation basin<br>• 240,000 gallon, 50-foot-wide, 180-foot-long, and 3-foot-deep percolation basin | The back-flush facilities would flush or cleans out organic material or bacterial growth, which would otherwise result in the lost pumping capacity of the injection wells. Back-flushed water would be conveyed to the percolation basin for storage. |
| Monitoring Wells | • Six Paso Robles Aquifer monitoring wells<br>• Six Santa Margarita Aquifer monitoring wells | Monitoring wells would be used to monitor project performance and compliance with State Board Division of Drinking Water regulations. The monitoring wells would also be used to satisfy regulatory requirements for monitoring of subsurface travel time, tracer testing, and other requirements for a groundwater replenishment project. |
| Electrical Power Supply and Instrumentation for GWR Injection Wells | • Electrical equipment<br>• Electrical control building (for backflush pumps) housing SCADA, electrical controls, pump drive, and adjacent transformer<br>• 400 square foot electrical control building housing the motor control center<br>• External electrical control cabinets<br>• Wiring<br>• Connections of electrical power and instrumentation and control facilities | Injection wells would require a permanent power supply to the site. |

# TECHNICAL MEMORANDUM

**TO: Bob Holden, MRWPCA** **DATE: September 16, 2015**

**FROM: Andrew A. Sterbenz, PE; Andrew Racz, EIT** **JOB #: MRWP.01.14:004**

**SUBJECT: Salinity Impacts to Elkhorn Slough resulting from surface water diversions for the Pure Water Monterey Groundwater Replenishment Project**

---

## INTRODUCTION:

This technical memo assesses the potential impact of the diversion of up to 16.6 cfs of freshwater inflows for the Pure Water Monterey Groundwater Replenishment Project (Project) on the salinity in Elkhorn Slough. Elkhorn Slough is a tidal estuary, receiving saltwater tidal inflow from Monterey Bay at the Moss Landing harbor inlet, as well as freshwater inflow from several surface streams, the largest of which is the Old Salinas River. These inputs mix within the estuary, and, along with precipitation, evaporation, and groundwater exchange, determine salinity levels in the slough. The following diversions are proposed from streams that feed the Old Salinas River: up to 6 cfs from the Reclamation Ditch near Salinas, up to 3 cfs from Tembladero Slough near Castroville, an average flow of 4.6 cfs from Blanco Drain, and 3 cfs of lost percolation pond inflow to the Salinas River. The minimum flow bypassing the proposed Project would be 2.0 cfs in the Salinas River and 1.0 cfs in the Reclamation Ditch/ Tembladero Slough, although higher flows are expected in most months.

## CURRENT SALINITY RANGE AND DISTRIBUTION IN ELKHORN SLOUGH

The Reclamation Ditch drains a watershed of approximately 157 square miles in and around Salinas. The Reclamation Ditch is a tributary of Tembladero Slough, which is itself a tributary of the Old Salinas River (OSR). The Old Salinas River, which also receives controlled flows of up to 120 cfs from the Salinas River Lagoon, discharges into Elkhorn Slough at the southern end of Moss Landing harbor.

As a result of complex branching geometry, tidal influence, and seasonally variable freshwater inputs, the salinity in Elkhorn Slough varies significantly with both time and location. Freshwater from the OSR discharges into Moss Landing harbor at low tide. It mixes with the outgoing tide in the main channel and is carried out into Monterey Bay. When the tide comes back in, any fresh/brackish water remaining in the main channel is pushed some distance up Elkhorn Slough by the rising tide, mixing to varying degrees as it travels. Depending on the season, water in the most inland reaches of the slough can be either fresher due to winter runoff, or saltier due to summer evaporation, than water in Monterey Bay, and also influences overall slough salinity when mixing occurs. The Land/Ocean Biogeochemical Observatory (LOBO) at MBARI has established a network of floating sensors that continuously record salinity at various locations in and around Elkhorn Slough (Figure 1).

**Figure 1:** Map of Elkhorn Slough. Significant features and LOBO sampling stations (pins) are identified.

**MIXING MODEL:**

Elkhorn Slough has a surface area of approximately 1.25 square miles and an average tidal range of about 3.5 feet, resulting in an average daily tidal flux of approximately 1400 cfs. The actual tidal range in any given tide cycle is governed by the position of the moon, sun, ocean currents, pressure systems and winds, and can vary between extremes of approximately 0.5 feet and 7 feet. Elkhorn Slough typically experiences two high and two low tides per day, such that the minimum 0.5-foot tidal cycle will always be accompanied by a second daily tide with a range of at least 2 feet. The model therefore uses a 2-foot range to calculate the minimum tidal inflow: approximately 800 cfs. The maximum modeled tidal flux caused by a 7' tide is approximately 2800 cfs. The salinity of inflowing Monterey Bay water varies within a narrow range of 32-34 parts per thousand (ppt). The average value of 33.4 ppt is used in the model.

The Old Salinas River is not gaged at its outlet to Moss Landing harbor, but inflows to the OSR from the Salinas River Lagoon are regulated by a slide gate. Typical summer flows are <15 cfs, and the gate is operated such that high flows never exceed 120 cfs. Flows on the Reclamation Ditch/Tembladero Slough (RD/TS) watershed are recorded by USGS gage #11152650, located at San Jon Road just north of Salinas. A scaling factor of 1.44 (based on relative watershed area and runoff characteristics) is applied to readings from this gage to estimate total flow in TS at its confluence with the OSR. The peak instantaneous gaged flow measured for the RD is 684 cfs. This occurred on 12/12/14 and was on the order of a 100-year event. Typical mean daily flows on the RD are <50 cfs during the wet season and <10 cfs during the summer months. Flows in the RD/TS are fresh, and an average salinity value of 1.5 ppt is used in the model.

A mixing model was created using the equation: $\mathbf{Q_1C_1 + Q_2C_2 = (Q_1 + Q_2)C_3}$, where $Q_1$ and $Q_2$ are the flow rates of two different inflows, and $C_1$ and $C_2$ are their respective salinities. The model solves for $C_3$, the resulting salinity of the mixed water body. Table 1 lists mixing model inputs and results for a tidal range of 3.5 feet and flow rates on the OSR ranging between 3 and 1000 cfs. Mixing assumes only two end-members (Monterey Bay Inflow and Old Salinas River Inflow) and is presumed to be conservative and complete. For the “Project” scenario, the Project Diversion is subtracted from OSR Inflow values prior to calculating mixing. The impact of the Project on Elkhorn Slough salinity (relative to No Project conditions) is expressed as both an absolute quantity and a percentage change. Data from Table 1 are plotted in Figure 2A. Figures 2B and 2C show model results for tidal ranges 7.0’ and 2.0’ respectively.

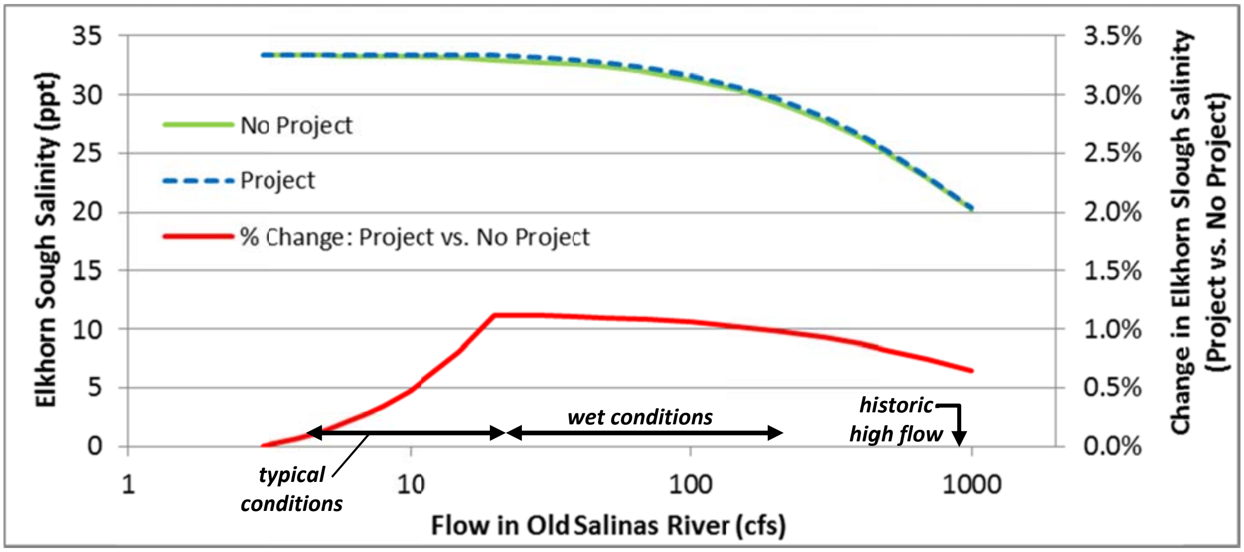
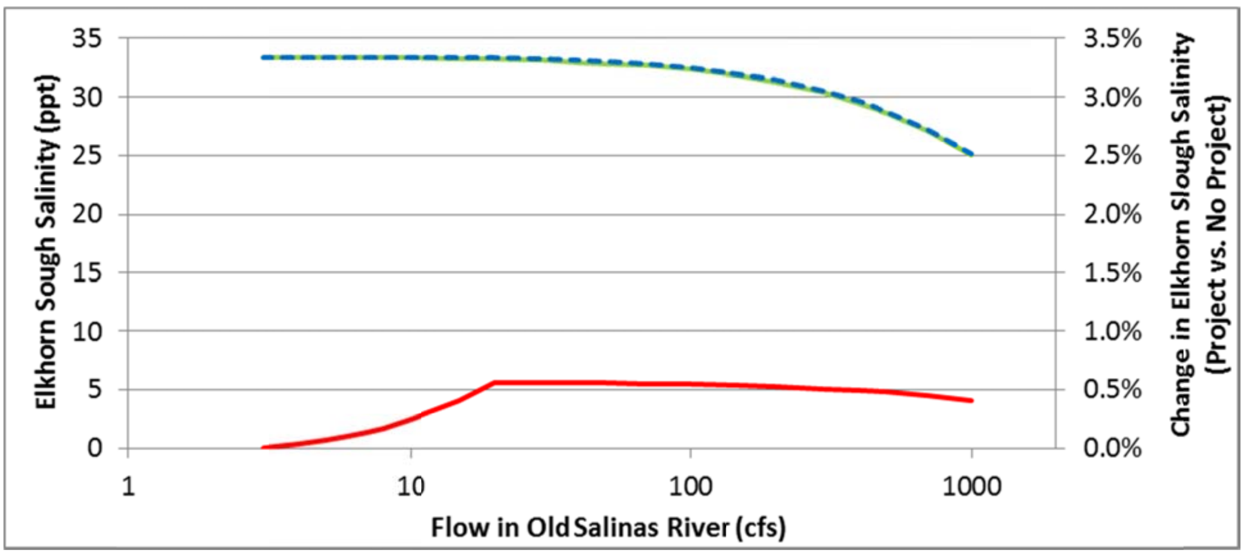
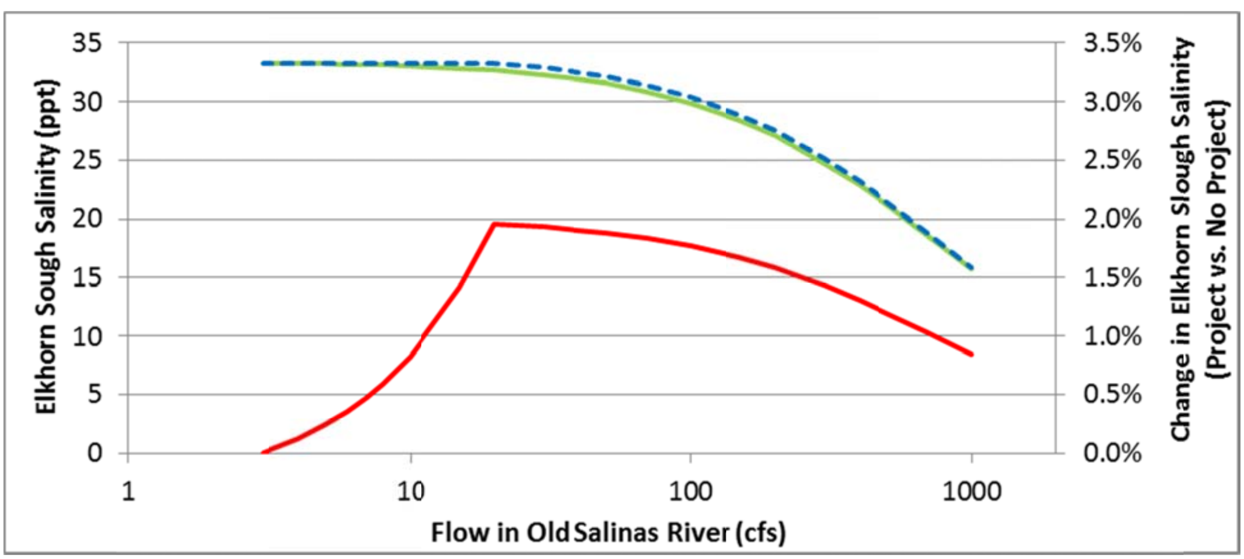
**Table 1:** Mixing model input and results for at tidal range of 3.5 feet.



(A)



(B)



(C)

**Figure 2:** Modeled salinity in Elkhorn Slough versus OSR inflow, for tidal ranges of (A) 1412 cfs [3.5' tide, average], (B) 2823 cfs [ 7.0' tide, maximum], and (C) 807 cfs [2.0' tide, minimum].

**DISCUSSION**:

During most of the year, the relative volume of inflow to Elkhorn Slough from the OSR is very small (<15 cfs) compared to inflows from Monterey Bay (approximate flow ranges indicated on Figure 2). At such a small mixing ratio, the water in Elkhorn Slough will not be appreciably freshened beyond background seawater values. Even though diversions may represent a large portion of the freshwater inflows under such conditions, the absolute quantity of freshwater entering Elkhorn Slough is so small that measurable differences between Project and No Project conditions are undetectable due to background variation.

Conversely, when flows from the OSR are high enough to appreciably drive down the salinity in Elkhorn Slough, the 16.6 cfs proposed to be diverted for the Groundwater Replenishment Project comprise such a small fraction of total freshwater inflows as to likewise have no detectable influence on the resulting salinity in Elkhorn Slough. Furthermore, during the time of year when flows tend to be high (winter wet season), demand for recycled water for irrigation is low, and surface water diversions would not be required.

Even at flow ranges where impact to Elkhorn Slough salinity is highest (approximately 10-50 cfs), the magnitude of the impact remains small: <0.4 ppt (1%) on the average tide, and in the most conservative case (2.0’ tidal range), still <0.7 ppt (2%). These salinity concentrations fall within the range of natural variability of Monterey Bay water, and are significantly smaller than the range of observed salinity concentrations in Elkhorn Slough. The Proposed Project would not detectably change the salinity of Elkhorn Slough on an average daily, weekly or monthly basis. The overall impact of the Project on Elkhorn Slough salinity is determined to be negligible.

# MEMORANDUM

| | | | |
|---|---|---|---|
| TO: | Bob Holden, MRWPCA | DATE: | September 16, 2015 |
| FROM: | Andrew Sterbenz, PE<br>Alison Imamura, AICP | JOB #: | MRWP.01.14 |
| SUBJECT: | Future RUWAP Recycled Water Urban Irrigation Use and Implications for CSIP Yields | | |

The purpose of this memorandum is to provide a discussion of the future Regional Urban Water Augmentation Project (RUWAP) Recycled Water Project for urban irrigation and its effects on Castroville Seawater Intrusion Project (CSIP) water supplies, with and without the Pure Water Monterey Groundwater Replenishment Project (Proposed Project).

Municipal wastewater is currently collected and conveyed to the MRWPCA Regional Treatment Plant (RTP) for primary and secondary treatment. The secondary-treated effluent is then either sent to the Salinas Valley Reclamation Plant (SVRP) for tertiary treatment, or it is discharged to the ocean. The tertiary-treated (recycled) water is supplied to the CSIP for agricultural irrigation. The Proposed Project would develop additional sources of water supply which would be conveyed to the RTP, increasing the supply of secondary treated effluent. A portion of this secondary-treated effluent would be sent to a new Advanced Water Treatment Facility (AWT Facility), and the remainder would be available for use by the SVRP/CSIP.

The Marina Coast Water District (MCWD) commented on the Draft Environmental Impact Report (DEIR) for the Proposed Project that its future urban recycled water project should be included in the supply analysis. The future RUWAP Recycled Water Project was addressed within the cumulative analyses in the DEIR. Cumulative projects were not included in the calculations of the Proposed Project's source water and use quantities. In the Proposed Project source water and use analysis, treated municipal wastewater that would be used by CSIP and the future RUWAP Recycled Water Project is appropriately assumed to *not* be available as influent for the AWT Facility during the peak irrigation demand months of April through September. The CSIP and the MCWD have existing contractual rights to the treated municipal wastewater, therefore the peak season volumes of water currently (i.e., based on the applicable, recent, 2009-2013 of monthly average flow data) discharged to the ocean outfall were considered available only to the SVRP for recycled water production. The average flows to the ocean outfall in the months of October through March exceed the combined projected demands of the GWR, the urban recycled water project, and the average CSIP groundwater use, and were therefore included in the analysis as available supplies for the AWT Facility in those months.

MCWD and FORA have jointly pursued the Regional Urban Water Augmentation Project that includes both a desalination component and a Recycled Water Project (the Recycled Water Project is herein referred to as the RUWAP) to develop additional urban irrigation water supply for redevelopment of the former Fort Ord. In accordance with existing agreements (see Table 4.18-5) among MRWPCA, MCWRA, and MCWD, MCWD has the right to purchase recycled water from the SVRP, up to the annual volume of municipal wastewater from MCWD's service area treated at the RTP. MCWD has agreed to limit their use of recycled water to 300 acre-feet during the period of April through September. MRWPCA had committed an additional 650 acre-feet during the period May through August in a Memorandum of Understanding between MCWD and MRWPCA (2009 RUWAP MOU). In the 2009 RUWAP MOU, MCWD and MRWPCA each committed their respective recycled water rights to the RUWAP. The RUWAP Recycled Water Project has not been implemented due to lack of funding, user commitments and immediate need for additional water supply, although the system is designed and sections of the recycled water pipeline have been installed in conjunction with road improvement projects. In addition, budget for completing the RUWAP facilities is not included in the MCWD 5-Year Capital Improvements Program. Therefore, the Draft EIR appropriately describes and analyzes the RUWAP as a reasonably foreseeable future project for purposes of its cumulative impacts analysis, rather than as an existing condition or a future background condition. A description of the proposed RUWAP was provided on page 4.1-13 and a cumulative analysis was provided within each topical section of Chapter 4; for example, combined impacts on water and wastewater systems are analyzed on pages 4.18-37 through 4.18-38. For the purpose of the Proposed Project's EIR, the existing flows into and out of the Regional Treatment Plant (RTP) are shown in Figure 1.

The RUWAP was originally planned and approved to provide 1,500 AFY of recycled water[1] including 1,200 AFY to the former Fort Ord and 300 AFY to areas outside the former Fort Ord served by the City of Seaside or CalAm. The RUWAP Project Description was updated in two EIR Addenda, including Addendum #2 that enabled MCWD to increase the RUWAP Recycled Water Project potential yield to up to 1,727 AFY of recycled water to provide the ability to serve more customers within their service area. In 2013, MPWMD and MRWPCA partnered to pursue the Proposed Project in part because the urban recycled water project was not scheduled for implementation, but primarily due to the issuance of a Cease and Desist Order by the SWRCB[2] regarding unauthorized diversions of Carmel River water by CalAm. Based on the FORA recycled water allocation approval in Resolution 07-10 (May 2007), the MCWD 2010 UWMP (MCWD, 2011), and the MCWD customer demand analyses in the Recycled Water Project Basis of Design Report (RMC, 2009), the RUWAP recycled water demand is assumed to be 1,427 AFY for the purpose of the cumulative analysis of water supplies in this EIR, with contractual rights to wastewater capped at the agreed upon 650 AF of MRWPCA rights and 300 AFY from MCWD's rights during the months of April through September.

Under the Agreements listed in Table 4.18-5 as amended in this Final EIR to include the 2009 RUWAP MOU, implementation of the RUWAP Recycled Water Project without implementation of the Proposed GWR Project would change the monthly availability of recycled water for CSIP customers in the peak demand months, as shown in Table 1. See Figure 2 for a RTP flow schematic of this scenario.

The RUWAP would require modifications of the SVRP to meet low winter demands, so the average annual recycled water deliveries to CSIP would increase by 1,350 AFY (i.e., 14,345 AFY compared to 12,939 AFY). The remaining groundwater use within CSIP would shift from winter to summer.

1 Final EIR for the Regional Urban Water Augmentation Project, adopted 5/25/2005

2 SWRCB Order Number WR 2009-0060

NOTES:

1. The RTP inflows have decreased from these values in 2014 and the first half of 2015 due to drought and associated conservation. These averages may be adjusted in the future using newer data; however, for the purposes of this EIR, the baseline wastewater flows were established as 2009 to 2013 as the Draft EIR preparation began in early 2014 and that was the most recent data available at that time.
2. CSIP use in this table is the lesser of either (a) the average monthly SVRP and groundwater use, or (b) the RTP Inflow minus RUWAP.

The Proposed Project's DEIR includes two product water pipeline options for conveying water from the proposed AWT Facility to the Injection Well Facilities site (Sections 2.9 and 2.12). One option is to follow the planned RUWAP recycled water main alignment, and the other follows the TAMC rail right-of-way through Marina into Seaside, and then uses street rights-of-way to General Jim Moore Blvd. Under the RUWAP alignment option, parallel pipelines would be constructed (the RUWAP pipeline for tertiary-treated recycled water delivery to urban irrigation customers and the Proposed Project pipeline for advanced treated water conveyance for injection in the Seaside Groundwater Basin). Joint use of a shared pipeline is beyond the scope of the Proposed Project. However, this memorandum analyzes the potential yields a shared pipeline may have in the event that MRWPCA and MCWD pursue this configuration in the future. Figures 3 and 4, attached, show conceptual flow diagrams of these two configurations. The shared pipeline configuration would require MCWD to accept advanced treated water instead of tertiary-treated recycled water, which may affect the volume of water available for urban reuse. The reduction of recycled water quantity compared to the full delivery is based on the planning assumption that a certain amount of the wastewater influent to the AWT would be lost during the treatment process. Approximately 19% of the influent treated wastewater would be discharged to the ocean as AWT Facility by-product, called reverse osmosis concentrate.

The following monthly urban recycled water demand scenarios have been modeled to estimate the quantities of recycled water available for CSIP and the RUWAP. These scenarios vary according to how the recycled water (including quantity and quality) is produced and delivered. Table 2, below, shows the results of the water quantity analysis in terms of RUWAP cumulative demands for each scenario, and Table 3, attached, shows the resultant monthly CSIP flows for each scenario.

- **Recycled Water (RW) Scenario:** In this scenario, the RUWAP pipeline and the Proposed Project Product Water Conveyance pipeline are constructed separately, as contemplated in the Proposed Project's EIR. MCWD's customers receive the full assumed urban irrigation demand of 1,427 AFY produced by the SVRP and delivered with the RUWAP tertiary-treated recycled water ("purple') pipeline when the RUWAP is constructed. Values in the table reflect the average monthly deliveries of urban recycled water. This scenario would require modifications to the SVRP to meet low winter recycled water demands (<5 mgd and <460 AF/month).[3] See Figure 3, Conceptual Flow Schematic of Proposed Project plus RUWAP with Separate Pipeline, for a conceptual flow diagram.

[3] The proposed SVRP modifications would also be required for the Proposed Project and are thus included in Chapter 2, Project Description (see pages 2-64 through 2-66).

- **Advanced Water Treatment Product (AWT Product) Scenario:** In this scenario, MCWD and MRWPCA would agree in the future to share the Proposed Project Product Water Conveyance pipeline, and the full assumed MCWD recycled water demand of 1,427 AFY would be produced by the Proposed Project AWT Facility and delivered as purified recycled water, conveyed in the same pipe with the product water intended for Seaside Basin subsurface application. Values in the table reflect the average monthly influent required at the AWT Facility to produce the quantities of delivered water reflected in the RW Scenario. Under the AWT Product scenario, the AWT process loss associated with the RUWAP yield would need to be supplied from new sources. This is referred to as the "Shared Pipeline Scenario with Allocations met as Product Water." See Figure 4, Conceptual Flow Schematic of Proposed Project plus RUWAP with Shared Pipeline, for a conceptual flow diagram.

- **Advanced Water Treatment Influent (AWT Influent) Scenario:** In this scenario, MCWD and MRWPCA would agree to share a pipeline as shown in Figure 4, and the 1,427 AFY of RUWAP supply would be used as influent to the AWT Facility, producing a net yield of 1,156 AFY of purified recycled water (due to the 19% process loss as RO concentrate). This supply would be conveyed in the same pipe with the Proposed Project's product water intended for Seaside Basin subsurface application. Under this scenario, none of the new sources are used to supplement the RUWAP production. Values in the table reflect the net monthly deliveries of urban recycled water. This is referred to as the "Shared Pipeline Scenario with Allocations met as AWT Facility Influent."

- **Initial Recycled Water Demand (Init-RW) Scenario:** This scenario shows initial RUWAP deliveries of 540 AFY, delivered as tertiary-treated recycled water consistent with Figure 1. This total only includes current urban irrigation demands at locations along the RUWAP trunk main (i.e., the customers who could be served without constructing additional lateral pipelines). This scenario is included to reflect that full RUWAP MOU deliveries are not required at this time. In this scenario, the RUWAP pipeline and the Proposed Project Product Water Conveyance pipeline are constructed separately. Values in the table reflect the average monthly deliveries of urban recycled water. This scenario would require modifications to the SVRP to meet low winter recycled water demands

- **Initial AWT Demand (Init-AWT) Scenario:** In this scenario, MCWD and MRWPCA would agree in the future to share a pipeline as shown in Figure 3, and the initial 540 AFY of recycled water would be produced for existing MCWD customers that are immediately adjacent to the proposed Product Water Pipeline alignment (i.e., the RUWAP pipeline option). Approximately 666 AFY of AWT Influent would be required to produce this water, accounting for the 19% loss of RO concentrate as ocean discharge. Values in the table reflect the average monthly influent that would be required at the AWT Facility to produce the quantities of delivered water reflected in scenario Init-RW.

**Table 2: RUWAP Urban Recycled Water Use by Treatment and Delivery Scenario (acre-feet)**

NOTES:
1. Values reflect urban recycled water deliveries.
2. Values reflect influent supply to the AWT Facility

The DEIR for the Proposed Project includes estimates of 4,750 AFY of additional water which would become available for use in the CSIP in average years, and 5,290 AFY in drought years with a developed reserve (Section 2.1.1.3 and Appendix B). Those estimations do not include the implementation of the RUWAP. In accordance with the certified RUWAP EIR, existing MCWD and FORA RUWAP approvals, and agreements listed in Table 4.18-5, the RUWAP would use the same supply of secondary-treated municipal wastewater as is used to supply recycled water to CSIP, so implementing the RUWAP would reduce the supply available to CSIP in the peak demand months. The Proposed Pure Water Monterey Project would more than offset these reductions (that is, the supply to CSIP from new sources is two to three times greater than the volume used by RUWAP in any month). Table 3 (attached) shows the MCWD and CSIP recycled water demands and use implications of the RUWAP Recycled Water Project in combination with the Proposed Project under the various scenarios described above. As can be seen, the AWT Influent scenario in which the pipeline would be shared has the same effect on CSIP yields as the separate pipeline scenarios (which is also the current or No Project condition). If the MRWPCA and MCWD were to agree in the future to share the pipeline under the AWT Product scenario, the net new supply available to CSIP would be reduced compared to the Proposed Project without RUWAP in the peak demand months by approximately 220 acre-feet; however, CSIP would still receive 2,370 acre-feet more recycled water in the peak demand months than without the Proposed Project, but with RUWAP.

Figures 5 to 14 (attached) show the monthly flows into and out of the RTP under the scenarios shown in Table 3. Each month is represented by two columns. The left column shows inflows to the RTP, including municipal wastewater and new sources developed under the Proposed Project. The right column shows outflows and uses, including recycled water from the SVRP to CSIP, recycled water from the SVRP to RUWAP, Advanced Treated Water to GWR, and unused and/or brine flows to the ocean outfall. The figures are stacked two per page, with the upper figure showing the scenario without the RUWAP, and the lower figure showing the same scenario with the RUWAP. In Figure 7, the drought year CSIP deliveries exceed the monthly RTP inflows due to differences in the way daily flows were calculated in the data set. Data tables similar to the analysis Tables 8, 9 and 10 from Appendix B of the DEIR, *Memorandum: Pure Water Monterey Groundwater Replenishment Project – Proposed Source Water Availability, Yield, and Use*, are attached with the supporting monthly calculations for each scenario. Because the results are identical for the separate pipeline and the AWT Influent scenarios, tables are not included for the AWT Influent scenario.

In Appendix B of the Draft EIR, as revised in this Final EIR, the Proposed Project source water analyses assumed no use of any treated municipal wastewater as influent to the Advanced Water Treatment Facility during the peak demand months of April through September, and prioritized use of existing treated municipal effluent quantities by CSIP year round. Due to their contractual rights to municipal wastewater, peak season volumes of water currently discharged to the ocean outfall were assumed to be used exclusively as influent to the SVRP for CSIP irrigation. In addition, the EIR assumes that CSIP could use additional source water flows for recycling up to the existing supplemental groundwater use (based on monthly averages, 2009-2013). As described above, MCWD's RUWAP was described and analyzed as a cumulative project, and the Draft EIR considered whether the Proposed Project would have a considerable contribution to any significant cumulative impacts of implementation of all past, present, and reasonably foreseeable future projects. The analysis of the combined effects of the Proposed Project plus cumulative projects was provided at the end of each topical section within Chapter 4 of the Draft EIR. Implementation of the RUWAP would necessitate implementation of the SVRP modifications to meet the urban irrigation demands, and the remainder of the Proposed Project improvements would increase the availability of wastewater for recycling at the RTP; therefore, even considering any new information about MCWD desiring to implement their RUWAP in their comments on the Draft, the cumulative conclusions in the Draft EIR are adequate and appropriate.

The construction impacts of the Proposed Project plus cumulative projects in the Draft EIR assumes that the RUWAP would not be built simultaneously with the Proposed Project due to schedule urgency of completing the Proposed Project and the limited existing demand for urban recycled water (estimated to be 540 AFY total or 360 AF during April through September). Therefore, the construction impacts of the two projects would not be additive such that any construction impacts of either project would be worsened by the other project. Overall construction impacts would be reduced if MRWPCA and MCWD agree in the future to share a single pipeline compared to constructing separate pipelines for RUWAP and the AWT product water. In particular, construction of a single pipeline for both uses would reduce construction equipment and vehicle use, reduce timeframes during which sensitive receptors near the RUWAP alignment would be exposed to construction impacts including air pollutants and noise/vibration, and traffic impacts would be reduced in terms of duration of temporary increased volumes and transportation disruptions. However, the Draft EIR's analysis (of both construction and operational impacts) assumed that the Proposed Project product water conveyance pipeline would be built sooner and that a potential future RUWAP pipeline would be constructed at a later date (i.e., not within the same timeframe nor with any overlapping timeframes). The impacts of constructing the RUWAP pipeline separately were addressed in the RUWAP EIR as amended in the two EIR Addenda (MCWD/DD&A, 2004 with Addenda in 2005 and 2007). As requested in comments on the Draft EIR, total recycled water yields for RUWAP customers and CSIP irrigators have been estimated under numerous implementation scenarios. The potential environmental impacts of future operation with a shared pipeline would be fully analyzed in a separate CEQA process.

| Normal/wet reserve full (Note 6) | | | | 3,500 | 0 | 17,880 | 3,500 | 540 | 17,440 | 1,427 | 16,710 | 1,156 | 16,940 | 540 | 17,530 | 1,427 | 16,940 |
| Drought year use reserve for CSIP | 15,470 | 1,427 | 15,700 | 2,500 | 0 | 21,200 | 2,500 | 540 | 20,680 | 1,427 | 19,830 | 1,156 | 20,090 | 540 | 20,780 | 1,427 | 20,090 |

**Notes:**

1a. This scenarios shows MCWD long-term demands (in accordance with the approved RUWAP Recycled Water Project and 2009 RUWAP MOU) and the resulting expected SVRP deliveries to CSIP without the Proposed Project implemented. This assumes the SVRP Modifications would be implemented as part of the RUWAP. T*he SVRP Modifications have not yet been built and thus are also a component of the Proposed Project* . Because there would be no drought reserve under this scenario, all normal/wet year deliveries would be the same.

1b. This scenario shows MCWD short-term demands and the expected SVRP deliveries to CSIP that might occur within the first 2 years of operation of the GWR Project with a pipeline shared with RUWAP. The estimated MCWD demand is based on existing customers along the RUWAP pipeline alignment- specifically, for Bayonet and Blackhorse Golf Courses, CSUMB sports fields, and Marina Heights streetscapes (MCWD, 2015).

1c. This scenario shows MCWD short-term demands and the resulting SVRP deliveries to CSIP that might occur within the first 2 years of operation of the GWR Project with separate pipelines for RUWAP and Proposed Project. The estimated MCWD demand is based on existing customers along the RUWAP pipeline alignment- specifically, for Bayonet and Blackhorse Golf Courses, CSUMB sports fields, and Marina Heights streetscapes (MCWD, 2015).

2a. This scenario shows the expected delivery to existing irrigation through CSIP plus planned/proposed demands from MCWD when adequate wastewater inflows from MCWD are sent to RTP to produce the full 2009 RUWAP MOU allotment (assuming shared pipeline for RUWAP and Proposed Project). Under this scenario, 1,761 AFY of MCWD wastewater inflow is needed for MCWD demands of 1,427 AFY due to 19% of treated water being discharged as reverse osmosis concentrate to the outfall. Specifically:

| AWT Facility Product Water Flows to meet 2009 RUWAP MOU Quantities | AWT Flows | | | |
|---|---|---|---|---|
| | **Influent** | **Product** | **Influent** | **Product** |
| | **APR-SEP (note 4)** | **APR-SEP (note 4)** | **Annual** | **Annual** |
| MCWD | 370 | 300 | 959 | 777 |
| MRWPCA | 802 | 650 | 802 | 650 |
| ***Total*** | ***1,172*** | ***950*** | ***1,761*** | ***1,427*** |

2b. This scenario shows the expected delivery to existing irrigation through CSIP plus planned/proposed demands when 950 AFY of wastewater inflows from MCWD are sent to RTP (assuming shared pipeline for RUWAP and Proposed Project). Under this scenario 1,427 AFY of MCWD wastewater inflow is used to produce 1,156 AFY for MCWD due to 19% of treated water being discharged as reverse osmosis concentrate to the outfall (AWT inflow for MCWD limited to 950 AF for April - September). Specifically:

| AWT Influent Flows limited to MCWD's 2009 RUWAP MOU Quantities | AWT Flows | | | |
|---|---|---|---|---|
| | **Influent** | **Product** | **Influent** | **Product** |
| | **APR-SEP (note 4)** | **APR-SEP (note 4)** | **Annual** | **Annual** |
| MCWD | 300 | 243 | 777 | 629.37 |
| MRWPCA | 650 | 526.5 | 650 | 526.5 |
| ***Total*** | ***950*** | ***770*** | ***1,427*** | ***1,156*** |

2c. Under this scenario, the assumed delivery to existing irrigation through CSIP plus planned/proposed demands when 950 AFY wastewater inflows from MCWD are sent to RTP. Under this scenario, 1,427 AFY of source water is needed for MCWD demands of 1,427 AFY because this scenario assumes MCWD recycled water comes from the SVRP and is delivered using separate pipelines.

3. Use of SVRP recycled water by CSIP irrigators for Normal/Wet years assumes the average SVRP deliveries to CSIP in 2009 – 2013. Use of SVRP recycled water for drought year conservatively assumes SVRP deliveries in 2013 as a baseline.

4. Under the 2009 RUWAP MOU, MCWD committed to provide 300 AFY from April to September while MRWPCA committed to provide 650 AFY from May to August. These calculations assume the 950 AFY spread across April to September and that MCWD's 300 AFY commitment would be used in April and September.

5. Since the CSIP system was built, CSIP irrigators have also received supply from CSIP supplemental groundwater wells (operated by MRWPCA) and, since 2009, from the Salinas River Diversion Facility (SRDF). These sources would continue to be available in the future under all scenarios (i.e., with no changes due to RUWAP nor the Proposed Project). The SRDF is expected to provide approximately 3,427 AFY to CSIP based on the full historical record of availability (a 5-year average, 2009 through 2013). Because the expected yields to CSIP from SRDF would not be affected by the Proposed Project nor by RUWAP, these yields are not included in the totals. Single drought year from SRDF to CSIP (2013) was 6,094 AFY; however, in multiple drought years no water is expected to be available from the SRDF (as demonstrated by years 2014 and 2015).

6. This asumes no diversion of at Tembladero Slough when the drought reserve is full.

## Table 4A: Source Water Analysis for the Pure Water Monterey Groundwater Replenishment Project

**Notes**

1 Presumes all facilities associated with diversions are completed.

2 Table 2-1, p. 5, Schaaf & Wheeler Consulting Engineers. Revised Draft, Groundwater Replenishment Project, Salinas River Inflow Impacts, Prepared for Denise Duffy & Associates, February 2015.

3 Volume of effluent from City of Salinas agricultural wash water to be directed into ponds 1,2,3, and the aeration pond for storage.

4 Average monthly flow from Revised Draft, Groundwater Replenishment Project, Salinas River Inflow Impacts, Prepared for Denise Duffy & Associates, February 2015.

5 Rainfall from Revised Draft, Groundwater Replenishment Project, Salinas River Inflow Impacts, Prepared for Denise Duffy & Associates, February 2015. Pond area presumed to be Ponds 1,2, 3 + Aeration lagoon. No rainfall/evaporation or storage assigned to drying beds.

6 Table 3, Todd Groundwater, Draft Memorandum, Pure Water Monterey Groundwater Replenishment Project: Impacts of Changes in Percolation at the Salinas Industrial Wastewater Treatment Facility on Groundwater and the Salinas River, February 11, 2015.

7 Table 4, Ibid. Also confirmed in MPWMD Industrial Ponds Percolation and Evaporation Technical Memorandum 2015-01, July 2015.

8 Ponds 1,2,3 and aeration basin hold up to 1,065 acre-feet (one foot of freeboard). If flow to ponds would exceed the maximum volume, it is presumed that excess flow can be diverted to the RIBs or drying beds or flow can be diverted to the RTP. Presume that pond storage goes to zero sometime during the year (shown here starting in July).

9 Max diversion = 6 cfs diversion. See REVISED DRAFT BLANCO DRAIN YIELD STUDY, Schaaf and Wheeler, December 2014.

10 Max. diversion = 6 cfs. See REVISED DRAFT RECLAMATION DITCH YIELD STUDY, Schaaf and Wheeler, March 2015. Note that flow figures shown here are a combination of flow estimates in the S&W analysis made for the 2 cfs instream requirement Jan-May and 1 cfs instream requirement for June-Dec.

11 Max. diversion = 3 cfs. See REVISED DRAFT RECLAMATION DITCH YIELD STUDY, Schaaf and Wheeler, March 2015. Figures shown here are the difference between the combined Davis Road/TS diversion with Seasonal Bypass. This presumes the preference is to remove flow at Davis Road first, rather than bypass flow to Tembaldero Slough.

12 Includes secondary effluent wastewater currently used to produce recycled water at the Salinas Valley Reclamation Project (SVRP), and additional amounts which may be used during periods of low demand (<5 mgd) with the proposed improvements to the SVRP.

13 New source waters not used by AWT will be available to SVRP for CSIP.

14 A drought reserve of up to 1,000 AF would be created over five years by producing 200 AFY additional product water from the GWR Project AWTF during winter months and storing the water in the Seaside Basin. This would establish a "water bank" that the CSIP can draw on in droughts. The drought reserve would allow flow at the RTP for the GWR Project to be temporarily reduced during critically dry periods, thus freeing up more of the newly available inflows to the RTP to be sent to the CSIP area. Extraction from the Seaside Basin would continue at the average rate to supply the Monterey Peninsula.

15 Average monthly RTP discharge, 2009-2013 (reported by MRWPCA).

16 Secondary treated municpal effluent not used for SVRP or the AWT.

17 Excess is calculated as Line 13 minus Lines 16 & 17

18 RUWAP supply comes from existing RTP inflows, demands reflect Phase 1 project.

## Table 4B: Source Water Analysis for the Pure Water Monterey Groundwater Replenishment Project

**Notes**

1 Presumes all facilities associated with diversions are completed.

2 Table 2-1, p. 5, Schaaf & Wheeler Consulting Engineers. Revised Draft, Groundwater Replenishment Project, Salinas River Inflow Impacts, Prepared for Denise Duffy & Associates, February 2015.

3 Volume of effluent from City of Salinas agricultural wash water to be directed into ponds 1,2,3, and the aeration pond for storage.

4 Average monthly flow from Revised Draft, Groundwater Replenishment Project, Salinas River Inflow Impacts, Prepared for Denise Duffy & Associates, February 2015.

5 Rainfall from Revised Draft, Groundwater Replenishment Project, Salinas River Inflow Impacts, Prepared for Denise Duffy & Associates, February 2015. Pond area presumed to be Ponds 1,2, 3 + Aeration lagoon. No rainfall/evaporation or storage assigned to drying beds.

6 Table 3, Todd Groundwater, Draft Memorandum, Pure Water Monterey Groundwater Replenishment Project: Impacts of Changes in Percolation at the Salinas Industrial Wastewater Treatment Facility on Groundwater and the Salinas River, February 11, 2015.

7 Table 4, Ibid. Also confirmed in MPWMD Industrial Ponds Percolation and Evaporation Technical Memorandum 2015-01, July 2015.

8 Ponds 1,2,3 and aeration basin hold up to 1,065 acre-feet (one foot of freeboard). If flow to ponds would exceed the maximum volume, it is presumed that excess flow can be diverted to the RIBs or drying beds or flow can be diverted to the RTP. Presume that pond storage goes to zero sometime during the year (shown here starting in July).

9 Max diversion = 6 cfs diversion. See REVISED DRAFT BLANCO DRAIN YIELD STUDY, Schaaf and Wheeler, December 2014.

10 Max. diversion = 6 cfs. See REVISED DRAFT RECLAMATION DITCH YIELD STUDY, Schaaf and Wheeler, March 2015. Note that flow figures shown here are a combination of flow estimates in the S&W analysis made for the 2 cfs instream requirement Jan-May and 1 cfs instream requirement for June-Dec.

11 Max. diversion = 3 cfs. See REVISED DRAFT RECLAMATION DITCH YIELD STUDY, Schaaf and Wheeler, March 2015. Figures shown here are the difference between the combined Davis Road/TS diversion with Seasonal Bypass. This presumes the preference is to remove flow at Davis Road first, rather than bypass flow to Tembaldero Slough.

12 Includes secondary effluent wastewater currently used to produce recycled water at the Salinas Valley Reclamation Project (SVRP), and additional amounts which may be used during periods of low demand (<5 mgd) with the proposed improvements to the SVRP.

13 New source waters not used by AWT will be available to SVRP for CSIP.

14 A drought reserve of up to 1,000 AF would be created over five years by producing 200 AFY additional product water from the GWR Project AWTF during winter months and storing the water in the Seaside Basin. This would establish a "water bank" that the CSIP can draw on in droughts. The drought reserve would allow flow at the RTP for the GWR Project to be temporarily reduced during critically dry periods, thus freeing up more of the newly available inflows to the RTP to be sent to the CSIP area. Extraction from the Seaside Basin would continue at the average rate to supply the Monterey Peninsula.

15 Average monthly RTP discharge, 2009-2013 (reported by MRWPCA).

16 Secondary treated municpal effluent not used for SVRP or the AWT.

17 Excess is calculated as Line 13 minus Lines 16 & 17

18 RUWAP supply comes from existing RTP inflows, demands reflect Phase 1 project.

**Notes**

1 Presumes all facilities associated with diversions are completed.

2 Table 2-1, p. 5, Schaaf & Wheeler Consulting Engineers. Revised Draft, Groundwater Replenishment Project, Salinas River Inflow Impacts, Prepared for Denise Duffy & Associates, February 2015.

3 Volume of effluent from City of Salinas agricultural wash water to be directed into ponds 1,2,3, and the aeration pond for storage.

4 Assume dry year at 1/3 the average monthly values from Revised Draft, Groundwater Replenishment Project, Salinas River Inflow Impacts, Prepared for Denise Duffy & Associates, February 2015.

5 Rainfall from Revised Draft, Groundwater Replenishment Project, Salinas River Inflow Impacts, Prepared for Denise Duffy & Associates, February 2015. Pond area presumed to be Ponds 1,2, 3 + Aeration lagoon. No rainfall/evaporation or storage assigned to drying beds.

6 Table 3, Todd Groundwater, Draft Memorandum, Pure Water Monterey Groundwater Replenishment Project: Impacts of Changes in Percolation at the Salinas Industrial Wastewater Treatment Facility on Groundwater and the Salinas River, February 11, 2015.

7 Table 4, Ibid. Also confirmed in MPWMD Industrial Ponds Percolation and Evaporation Technical Memorandum 2015-01, July 2015.

8 Ponds 1,2,3 and aeration basin hold up to 1,065 acre-feet (one foot of freeboard). If flow to ponds would exceed the maximum volume, it is presumed that excess flow can be diverted to the RIBs or drying beds or flow can be diverted to the RTP. Presume that pond storage goes to zero sometime during the year (shown here starting in July).

9 Max diversion = 6 cfs diversion. See REVISED DRAFT BLANCO DRAIN YIELD STUDY, Schaaf and Wheeler, December 2014.

10 Max. diversion = 6 cfs. See REVISED DRAFT RECLAMATION DITCH YIELD STUDY, Schaaf and Wheeler, March 2015. Note that flow figures shown here are a combination of flow estimates in the S&W analysis made for the 2 cfs instream requirement Jan-May and 1 cfs instream requirement for June-Dec.

11 Max. diversion = 3 cfs. See REVISED DRAFT RECLAMATION DITCH YIELD STUDY, Schaaf and Wheeler, March 2015. Figures shown here are the difference between the combined Davis Road/TS diverison with Seasonal Bypass. This presumes the preference is to remove flow at Davis Road first, rather than bypass flow to Tembaldero Slough.

12 Includes secondary effluent wastewater currently used to produce recycled water at the Salinas Valley Reclamation Project (SVRP), and additional amounts which may be used during periods of low demand (<5 mgd) with the proposed improvements to the SVRP.

13 New source waters not used by AWT will be available to SVRP for CSIP.

14 A drought reserve of up to 1,000 AF would be created over five years by producing 200 AFY additional product water from the GWR Project AWTF during winter months and storing the water in the Seaside Basin. This would establish a "water bank" that the CSIP can draw on in droughts. The drought reserve would allow flow at the RTP for the GWR Project to be temporarily reduced during critically dry periods, thus freeing up more of the newly available inflows to the RTP to be sent to the CSIP area. Extraction from the Seaside Basin would continue at the average rate to supply the Monterey Peninsula.

15 Monthly RTP discharge during critically dry year (2013), reported by MRWPCA

16 Secondary treated municpal effluent not used for SVRP or the AWT.

17 Excess is calculated as Line 13 minus Lines 16 & 17

18 RUWAP supply comes from existing RTP inflows, demands reflect Phase 1 project.

**Notes**

1 Presumes all facilities associated with diversions are completed.

2 Table 2-1, p. 5, Schaaf & Wheeler Consulting Engineers. Revised Draft, Groundwater Replenishment Project, Salinas River Inflow Impacts, Prepared for Denise Duffy & Associates, February 2015.

3 Volume of effluent from City of Salinas agricultural wash water to be directed into ponds 1,2,3, and the aeration pond for storage.

4 Average monthly flow from Revised Draft, Groundwater Replenishment Project, Salinas River Inflow Impacts, Prepared for Denise Duffy & Associates, February 2015.

5 Rainfall from Revised Draft, Groundwater Replenishment Project, Salinas River Inflow Impacts, Prepared for Denise Duffy & Associates, February 2015. Pond area presumed to be Ponds 1,2, 3 + Aeration lagoon. No rainfall/evaporation or storage assigned to drying beds.

6 Table 3, Todd Groundwater, Draft Memorandum, Pure Water Monterey Groundwater Replenishment Project: Impacts of Changes in Percolation at the Salinas Industrial Wastewater Treatment Facility on Groundwater and the Salinas River, February 11, 2015.

7 Table 4, Ibid.

8 Ponds 1,2,3 and aeration basin hold up to 1,065 acre-feet (one foot of freeboard). If flow to ponds would exceed the maximum volume, it is presumed that excess flow can be diverted to the RIBs or drying beds or flow can be diverted to the RTP. Presume that pond storage goes to zero sometime during the year (shown here starting in July).

9 Table 4, Ibid. Also confirmed in MPWMD Industrial Ponds Percolation and Evaporation Technical Memorandum 2015-01, July 2015.

10 Max. diversion = 6 cfs. See REVISED DRAFT RECLAMATION DITCH YIELD STUDY, Schaaf and Wheeler, March 2015. Note that flow figures shown here are a combination of flow estimates in the S&W analysis made for the 2 cfs instream requirement Jan-May and 1 cfs instream requirement for June-Dec.

11 Max. diversion = 3 cfs. See REVISED DRAFT RECLAMATION DITCH YIELD STUDY, Schaaf and Wheeler, March 2015. Figures shown here are the difference between the combined Davis Road/TS diversion with Seasonal Bypass. This presumes the preference is to remove flow at Davis Road first, rather than bypass flow to Tembaldero Slough.

12 Includes secondary effluent wastewater currently used to produce recycled water at the Salinas Valley Reclamation Project (SVRP), and additional amounts which may be used during periods of low demand (<5 mgd) with the proposed improvements to the SVRP.

13 New source waters not used by AWT will be available to SVRP for CSIP.

14 A drought reserve of up to 1,000 AF would be created over five years by producing 200 AFY additional product water from the GWR Project AWTF during winter months and storing the water in the Seaside Basin. This would establish a "water bank" that the CSIP can draw on in droughts. The drought reserve would allow flow at the RTP for the GWR Project to be temporarily reduced during critically dry periods, thus freeing up more of the newly available inflows to the RTP to be sent to the CSIP area. Extraction from the Seaside Basin would continue at the average rate to supply the Monterey Peninsula.

15 Average monthly RTP discharge, 2009-2013 (reported by MRWPCA).

16 Secondary treated municpal effluent not used for SVRP or the AWT.

17 Excess is calculated as Line 13 minus Lines 15 & 16

18 RUWAP supply comes from existing RTP inflows, demands reflect Phase 1 project.

## Table 5B: Source Water Analysis for the Pure Water Monterey Groundwater Replenishment Project

### Diversion Pattern for a Normal Water Year with a Full Reserve, Full RUWAP Demand as AWT Product

2 Table 2-1, p. 5, Schaaf & Wheeler Consulting Engineers. Revised Draft, Groundwater Replenishment Project, Salinas River Inflow Impacts, Prepared for Denise Duffy & Associates, February 2015.

3 Volume of effluent from City of Salinas agricultural wash water to be directed into ponds 1,2,3, and the aeration pond for storage.

4 Average monthly flow from Revised Draft, Groundwater Replenishment Project, Salinas River Inflow Impacts, Prepared for Denise Duffy & Associates, February 2015.

5 Rainfall from Revised Draft, Groundwater Replenishment Project, Salinas River Inflow Impacts, Prepared for Denise Duffy & Associates, February 2015. Pond area presumed to be Ponds 1,2, 3 + Aeration lagoon. No rainfall/evaporation or storage assigned to drying beds.

6 Table 3, Todd Groundwater, Draft Memorandum, Pure Water Monterey Groundwater Replenishment Project: Impacts of Changes in Percolation at the Salinas Industrial Wastewater Treatment Facility on Groundwater and the Salinas River, February 11, 2015.

7 Table 4, Ibid.

8 Ponds 1,2,3 and aeration basin hold up to 1,065 acre-feet (one foot of freeboard). If flow to ponds would exceed the maximum volume, it is presumed that excess flow can be diverted to the RIBs or drying beds or flow can be diverted to the RTP. Presume that pond storage goes to zero sometime during the year (shown here starting in July).

9 Table 4, Ibid. Also confirmed in MPWMD Industrial Ponds Percolation and Evaporation Technical Memorandum 2015-01, July 2015.

10 Max. diversion = 6 cfs. See REVISED DRAFT RECLAMATION DITCH YIELD STUDY, Schaaf and Wheeler, March 2015. Note that flow figures shown here are a combination of flow estimates in the S&W analysis made for the 2 cfs instream requirement Jan-May and 1 cfs instream requirement for June-Dec.

11 Max. diversion = 3 cfs. See REVISED DRAFT RECLAMATION DITCH YIELD STUDY, Schaaf and Wheeler, March 2015. Figures shown here are the difference between the combined Davis Road/TS diversion with Seasonal Bypass. This presumes the preference is to remove flow at Davis Road first, rather than bypass flow to Tembaldero Slough.

12 Includes secondary effluent wastewater currently used to produce recycled water at the Salinas Valley Reclamation Project (SVRP), and additional amounts which may be used during periods of low demand (<5 mgd) with the proposed improvements to the SVRP.

13 New source waters not used by AWT will be available to SVRP for CSIP.

14 A drought reserve of up to 1,000 AF would be created over five years by producing 200 AFY additional product water from the GWR Project AWTF during winter months and storing the water in the Seaside Basin. This would establish a "water bank" that the CSIP can draw on in droughts. The drought reserve would allow flow at the RTP for the GWR Project to be temporarily reduced during critically dry periods, thus freeing up more of the newly available inflows to the RTP to be sent to the CSIP area. Extraction from the Seaside Basin would continue at the average rate to supply the Monterey Peninsula.

15 Average monthly RTP discharge, 2009-2013 (reported by MRWPCA).

16 Secondary treated municpal effluent not used for SVRP or the AWT.

17 Excess is calculated as Line 13 minus Lines 15 & 16

18 RUWAP supply comes from existing RTP inflows, demands reflect Phase 1 project.

## Table 5C: Source Water Analysis for the Pure Water Monterey Groundwater Replenishment Project

**Diversion Pattern for a Drought Year, Starting with a Full Drought Reserve, Full RUWAP Demand as AWT Product**

**Notes**

1 Presumes all facilities associated with diversions are completed.

2 Table 2-1, p. 5, Schaaf & Wheeler Consulting Engineers. Revised Draft, Groundwater Replenishment Project, Salinas River Inflow Impacts, Prepared for Denise Duffy & Associates, February 2015.

3 Volume of effluent from City of Salinas agricultural wash water to be directed into ponds 1,2,3, and the aeration pond for storage.

4 Assume dry year at 1/3 the average monthly values from Revised Draft, Groundwater Replenishment Project, Salinas River Inflow Impacts, Prepared for Denise Duffy & Associates, February 2015.

5 Rainfall from Revised Draft, Groundwater Replenishment Project, Salinas River Inflow Impacts, Prepared for Denise Duffy & Associates, February 2015. Pond area presumed to be Ponds 1,2, 3 + Aeration lagoon. No rainfall/evaporation or storage assigned to drying beds.

6 Table 3, Todd Groundwater, Draft Memorandum, Pure Water Monterey Groundwater Replenishment Project: Impacts of Changes in Percolation at the Salinas Industrial Wastewater Treatment Facility on Groundwater and the Salinas River, February 11, 2015.

7 Table 4, Ibid.

8 Ponds 1,2,3 and aeration basin hold up to 1,065 acre-feet (one foot of freeboard). If flow to ponds would exceed the maximum volume, it is presumed that excess flow can be diverted to the RIBs or drying beds or flow can be diverted to the RTP. Presume that pond storage goes to zero sometime during the year (shown here starting in July).

9 Table 4, Ibid. Also confirmed in MPWMD Industrial Ponds Percolation and Evaporation Technical Memorandum 2015-01, July 2015.

10 Max. diversion = 6 cfs. See REVISED DRAFT RECLAMATION DITCH YIELD STUDY, Schaaf and Wheeler, March 2015. Note that flow figures shown here are a combination of flow estimates in the S&W analysis made for the 2 cfs instream requirement Jan-May and 1 cfs instream requirement for June-Dec.

11 Max. diversion = 3 cfs. See REVISED DRAFT RECLAMATION DITCH YIELD STUDY, Schaaf and Wheeler, March 2015. Figures shown here are the difference between the combined Davis Road/TS diversion with Seasonal Bypass. This presumes the preference is to remove flow at Davis Road first, rather than bypass flow to Tembaldero Slough.

12 Includes secondary effluent wastewater currently used to produce recycled water at the Salinas Valley Reclamation Project (SVRP), and additional amounts which may be used during periods of low demand (<5 mgd) with the proposed improvements to the SVRP.

13 New source waters not used by AWT will be available to SVRP for CSIP.

14 A drought reserve of up to 1,000 AF would be created over five years by producing 200 AFY additional product water from the GWR Project AWTF during winter months and storing the water in the Seaside Basin. This would establish a "water bank" that the CSIP can draw on in droughts. The drought reserve would allow flow at the RTP for the GWR Project to be temporarily reduced during critically dry periods, thus freeing up more of the newly available inflows to the RTP to be sent to the CSIP area. Extraction from the Seaside Basin would continue at the average rate to supply the Monterey Peninsula.

15 Monthly RTP discharge during critically dry year (2013), reported by MRWPCA

16 Secondary treated municpal effluent not used for SVRP or the AWT.

17 Excess is calculated as Line 13 minus Lines 15 & 16

18 RUWAP supply comes from existing RTP inflows, demands reflect Phase 1 project.

## Table 6A: Source Water Analysis for the Pure Water Monterey Groundwater Replenishment Project

### Diversion Patterns for a Normal Water Year, Building a Drought Reserve, Initial RUWAP Demand as Recycled Water

**Notes**

1 Presumes all facilities associated with diversions are completed.

2 Table 2-1, p. 5, Schaaf & Wheeler Consulting Engineers. Revised Draft, Groundwater Replenishment Project, Salinas River Inflow Impacts, Prepared for Denise Duffy & Associates, February 2015.

3 Volume of effluent from City of Salinas agricultural wash water to be directed into ponds 1,2,3, and the aeration pond for storage.

4 Average monthly flow from Revised Draft, Groundwater Replenishment Project, Salinas River Inflow Impacts, Prepared for Denise Duffy & Associates, February 2015.

5 Rainfall from Revised Draft, Groundwater Replenishment Project, Salinas River Inflow Impacts, Prepared for Denise Duffy & Associates, February 2015. Pond area presumed to be Ponds 1,2, 3 + Aeration lagoon. No rainfall/evaporation or storage assigned to drying beds.

6 Table 3, Todd Groundwater, Draft Memorandum, Pure Water Monterey Groundwater Replenishment Project: Impacts of Changes in Percolation at the Salinas Industrial Wastewater Treatment Facility on Groundwater and the Salinas River, February 11, 2015.

7 Table 4, Ibid. Also confirmed in MPWMD Industrial Ponds Percolation and Evaporation Technical Memorandum 2015-01, July 2015.

8 Ponds 1,2,3 and aeration basin hold up to 1,065 acre-feet (one foot of freeboard). If flow to ponds would exceed the maximum volume, it is presumed that excess flow can be diverted to the RIBs or drying beds or flow can be diverted to the RTP. Presume that pond storage goes to zero sometime during the year (shown here starting in July).

9 Max diversion = 6 cfs diversion. See REVISED DRAFT BLANCO DRAIN YIELD STUDY, Schaaf and Wheeler, December 2014.

10 Max. diversion = 6 cfs. See REVISED DRAFT RECLAMATION DITCH YIELD STUDY, Schaaf and Wheeler, March 2015. Note that flow figures shown here are a combination of flow estimates in the S&W analysis made for the 2 cfs instream requirement Jan-May and 1 cfs instream requirement for June-Dec.

11 Max. diversion = 3 cfs. See REVISED DRAFT RECLAMATION DITCH YIELD STUDY, Schaaf and Wheeler, March 2015. Figures shown here are the difference between the combined Davis Road/TS diversion with Seasonal Bypass. This presumes the preference is to remove flow at Davis Road first, rather than bypass flow to Tembaldero Slough.

12 Includes secondary effluent wastewater currently used to produce recycled water at the Salinas Valley Reclamation Project (SVRP), and additional amounts which may be used during periods of low demand (<5 mgd) with the proposed improvements to the SVRP.

13 New source waters not used by AWT will be available to SVRP for CSIP.

14 A drought reserve of up to 1,000 AF would be created over five years by producing 200 AFY additional product water from the GWR Project AWTF during winter months and storing the water in the Seaside Basin. This would establish a "water bank" that the CSIP can draw on in droughts. The drought reserve would allow flow at the RTP for the GWR Project to be temporarily reduced during critically dry periods, thus freeing up more of the newly available inflows to the RTP to be sent to the CSIP area. Extraction from the Seaside Basin would continue at the average rate to supply the Monterey Peninsula.

15 Average monthly RTP discharge, 2009-2013 (reported by MRWPCA).

16 Secondary treated municpal effluent not used for SVRP or the AWT.

17 Excess is calculated as Line 13 minus Lines 16 & 17

18 RUWAP supply comes from existing RTP inflows, demands reflect existing urban irrigation customers along trunk main.

**Notes**

1 Presumes all facilities associated with diversions are completed.

2 Table 2-1, p. 5, Schaaf & Wheeler Consulting Engineers. Revised Draft, Groundwater Replenishment Project, Salinas River Inflow Impacts, Prepared for Denise Duffy & Associates, February 2015.

3 Volume of effluent from City of Salinas agricultural wash water to be directed into ponds 1,2,3, and the aeration pond for storage.

4 Average monthly flow from Revised Draft, Groundwater Replenishment Project, Salinas River Inflow Impacts, Prepared for Denise Duffy & Associates, February 2015.

5 Rainfall from Revised Draft, Groundwater Replenishment Project, Salinas River Inflow Impacts, Prepared for Denise Duffy & Associates, February 2015. Pond area presumed to be Ponds 1,2, 3 + Aeration lagoon. No rainfall/evaporation or storage assigned to drying beds.

6 Table 3, Todd Groundwater, Draft Memorandum, Pure Water Monterey Groundwater Replenishment Project: Impacts of Changes in Percolation at the Salinas Industrial Wastewater Treatment Facility on Groundwater and the Salinas River, February 11, 2015.

7 Table 4, Ibid. Also confirmed in MPWMD Industrial Ponds Percolation and Evaporation Technical Memorandum 2015-01, July 2015.

8 Ponds 1,2,3 and aeration basin hold up to 1,065 acre-feet (one foot of freeboard). If flow to ponds would exceed the maximum volume, it is presumed that excess flow can be diverted to the RIBs or drying beds or flow can be diverted to the RTP. Presume that pond storage goes to zero sometime during the year (shown here starting in July).

9 Max diversion = 6 cfs diversion. See REVISED DRAFT BLANCO DRAIN YIELD STUDY, Schaaf and Wheeler, December 2014.

10 Max. diversion = 6 cfs. See REVISED DRAFT RECLAMATION DITCH YIELD STUDY, Schaaf and Wheeler, March 2015. Note that flow figures shown here are a combination of flow estimates in the S&W analysis made for the 2 cfs instream requirement Jan-May and 1 cfs instream requirement for June-Dec.

11 Max. diversion = 3 cfs. See REVISED DRAFT RECLAMATION DITCH YIELD STUDY, Schaaf and Wheeler, March 2015. Figures shown here are the difference between the combined Davis Road/TS diverison with Seasonal Bypass. This presumes the preference is to remove flow at Davis Road first, rather than bypass flow to Tembaldero Slough.

12 Includes secondary effluent wastewater currently used to produce recycled water at the Salinas Valley Reclamation Project (SVRP), and additional amounts which may be used during periods of low demand (<5 mgd) with the proposed improvements to the SVRP.

13 New source waters not used by AWT will be available to SVRP for CSIP.

14 A drought reserve of up to 1,000 AF would be created over five years by producing 200 AFY additional product water from the GWR Project AWTF during winter months and storing the water in the Seaside Basin. This would establish a "water bank" that the CSIP can draw on in droughts. The drought reserve would allow flow at the RTP for the GWR Project to be temporarily reduced during critically dry periods, thus freeing up more of the newly available inflows to the RTP to be sent to the CSIP area. Extraction from the Seaside Basin would continue at the average rate to supply the Monterey Peninsula.

15 Average monthly RTP discharge, 2009-2013 (reported by MRWPCA).

16 Secondary treated municpal effluent not used for SVRP or the AWT.

17 Excess is calculated as Line 13 minus Lines 16 & 17

18 RUWAP supply comes from existing RTP inflows, demands reflect existing urban irrigation customers along trunk main.

**Notes**

1 Presumes all facilities associated with diversions are completed.

2 Table 2-1, p. 5, Schaaf & Wheeler Consulting Engineers. Revised Draft, Groundwater Replenishment Project, Salinas River Inflow Impacts, Prepared for Denise Duffy & Associates, February 2015.

3 Volume of effluent from City of Salinas agricultural wash water to be directed into ponds 1,2,3, and the aeration pond for storage.

4 Assume dry year at 1/3 the average monthly values from Revised Draft, Groundwater Replenishment Project, Salinas River Inflow Impacts, Prepared for Denise Duffy & Associates, February 2015.

5 Rainfall from Revised Draft, Groundwater Replenishment Project, Salinas River Inflow Impacts, Prepared for Denise Duffy & Associates, February 2015. Pond area presumed to be Ponds 1,2, 3 + Aeration lagoon. No rainfall/evaporation or storage assigned to drying beds.

6 Table 3, Todd Groundwater, Draft Memorandum, Pure Water Monterey Groundwater Replenishment Project: Impacts of Changes in Percolation at the Salinas Industrial Wastewater Treatment Facility on Groundwater and the Salinas River, February 11, 2015.

7 Table 4, Ibid. Also confirmed in MPWMD Industrial Ponds Percolation and Evaporation Technical Memorandum 2015-01, July 2015.

8 Ponds 1,2,3 and aeration basin hold up to 1,065 acre-feet (one foot of freeboard). If flow to ponds would exceed the maximum volume, it is presumed that excess flow can be diverted to the RIBs or drying beds or flow can be diverted to the RTP. Presume that pond storage goes to zero sometime during the year (shown here starting in July).

9 Max diversion = 6 cfs diversion. See REVISED DRAFT BLANCO DRAIN YIELD STUDY, Schaaf and Wheeler, December 2014.

10 Max. diversion = 6 cfs. See REVISED DRAFT RECLAMATION DITCH YIELD STUDY, Schaaf and Wheeler, March 2015. Note that flow figures shown here are a combination of flow estimates in the S&W analysis made for the 2 cfs instream requirement Jan-May and 1 cfs instream requirement for June-Dec.

11 Max. diversion = 3 cfs. See REVISED DRAFT RECLAMATION DITCH YIELD STUDY, Schaaf and Wheeler, March 2015. Figures shown here are the difference between the combined Davis Road/TS diverison with Seasonal Bypass. This presumes the preference is to remove flow at Davis Road first, rather than bypass flow to Tembaldero Slough.

12 Includes secondary effluent wastewater currently used to produce recycled water at the Salinas Valley Reclamation Project (SVRP), and additional amounts which may be used during periods of low demand (<5 mgd) with the proposed improvements to the SVRP.

13 New source waters not used by AWT will be available to SVRP for CSIP.

14 A drought reserve of up to 1,000 AF would be created over five years by producing 200 AFY additional product water from the GWR Project AWTF during winter months and storing the water in the Seaside Basin. This would establish a "water bank" that the CSIP can draw on in droughts. The drought reserve would allow flow at the RTP for the GWR Project to be temporarily reduced during critically dry periods, thus freeing up more of the newly available inflows to the RTP to be sent to the CSIP area. Extraction from the Seaside Basin would continue at the average rate to supply the Monterey Peninsula.

15 Monthly RTP discharge during critically dry year (2013), reported by MRWPCA

16 Secondary treated municpal effluent not used for SVRP or the AWT.

17 Excess is calculated as Line 13 minus Lines 16 & 17

18 RUWAP supply comes from existing RTP inflows, demands reflect existing urban irrigation customers along trunk main.

**Notes**

1 Presumes all facilities associated with diversions are completed.

2 Table 2-1, p. 5, Schaaf & Wheeler Consulting Engineers. Revised Draft, Groundwater Replenishment Project, Salinas River Inflow Impacts, Prepared for Denise Duffy & Associates, February 2015.

3 Volume of effluent from City of Salinas agricultural wash water to be directed into ponds 1,2,3, and the aeration pond for storage.

4 Average monthly flow from Revised Draft, Groundwater Replenishment Project, Salinas River Inflow Impacts, Prepared for Denise Duffy & Associates, February 2015.

5 Rainfall from Revised Draft, Groundwater Replenishment Project, Salinas River Inflow Impacts, Prepared for Denise Duffy & Associates, February 2015. Pond area presumed to be Ponds 1,2, 3 + Aeration lagoon. No rainfall/evaporation or storage assigned to drying beds.

6 Table 3, Todd Groundwater, Draft Memorandum, Pure Water Monterey Groundwater Replenishment Project: Impacts of Changes in Percolation at the Salinas Industrial Wastewater Treatment Facility on Groundwater and the Salinas River, February 11, 2015.

7 Table 4, Ibid.

8 Ponds 1,2,3 and aeration basin hold up to 1,065 acre-feet (one foot of freeboard). If flow to ponds would exceed the maximum volume, it is presumed that excess flow can be diverted to the RIBs or drying beds or flow can be diverted to the RTP. Presume that pond storage goes to zero sometime during the year (shown here starting in July).

9 Table 4, Ibid. Also confirmed in MPWMD Industrial Ponds Percolation and Evaporation Technical Memorandum 2015-01, July 2015.

10 Max. diversion = 6 cfs. See REVISED DRAFT RECLAMATION DITCH YIELD STUDY, Schaaf and Wheeler, March 2015. Note that flow figures shown here are a combination of flow estimates in the S&W analysis made for the 2 cfs instream requirement Jan-May and 1 cfs instream requirement for June-Dec.

11 Max. diversion = 3 cfs. See REVISED DRAFT RECLAMATION DITCH YIELD STUDY, Schaaf and Wheeler, March 2015. Figures shown here are the difference between the combined Davis Road/TS diversion with Seasonal Bypass. This presumes the preference is to remove flow at Davis Road first, rather than bypass flow to Tembaldero Slough.

12 Includes secondary effluent wastewater currently used to produce recycled water at the Salinas Valley Reclamation Project (SVRP), and additional amounts which may be used during periods of low demand (<5 mgd) with the proposed improvements to the SVRP.

13 New source waters not used by AWT will be available to SVRP for CSIP.

14 A drought reserve of up to 1,000 AF would be created over five years by producing 200 AFY additional product water from the GWR Project AWTF during winter months and storing the water in the Seaside Basin. This would establish a "water bank" that the CSIP can draw on in droughts. The drought reserve would allow flow at the RTP for the GWR Project to be temporarily reduced during critically dry periods, thus freeing up more of the newly available inflows to the RTP to be sent to the CSIP area. Extraction from the Seaside Basin would continue at the average rate to supply the Monterey Peninsula.

15 Average monthly RTP discharge, 2009-2013 (reported by MRWPCA).

16 Secondary treated municpal effluent not used for SVRP or the AWT.

17 Excess is calculated as Line 13 minus Lines 15 & 16

18 RUWAP supply comes from existing RTP inflows, demands reflect existing urban irrigation customers along trunk main.

**Notes**

1 Presumes all facilities associated with diversions are completed.

2 Table 2-1, p. 5, Schaaf & Wheeler Consulting Engineers. Revised Draft, Groundwater Replenishment Project, Salinas River Inflow Impacts, Prepared for Denise Duffy & Associates, February 2015.

3 Volume of effluent from City of Salinas agricultural wash water to be directed into ponds 1,2,3, and the aeration pond for storage.

4 Average monthly flow from Revised Draft, Groundwater Replenishment Project, Salinas River Inflow Impacts, Prepared for Denise Duffy & Associates, February 2015.

5 Rainfall from Revised Draft, Groundwater Replenishment Project, Salinas River Inflow Impacts, Prepared for Denise Duffy & Associates, February 2015. Pond area presumed to be Ponds 1,2, 3 + Aeration lagoon. No rainfall/evaporation or storage assigned to drying beds.

6 Table 3, Todd Groundwater, Draft Memorandum, Pure Water Monterey Groundwater Replenishment Project: Impacts of Changes in Percolation at the Salinas Industrial Wastewater Treatment Facility on Groundwater and the Salinas River, February 11, 2015.

7 Table 4, Ibid.

8 Ponds 1,2,3 and aeration basin hold up to 1,065 acre-feet (one foot of freeboard). If flow to ponds would exceed the maximum volume, it is presumed that excess flow can be diverted to the RIBs or drying beds or flow can be diverted to the RTP. Presume that pond storage goes to zero sometime during the year (shown here starting in July).

9 Table 4, Ibid. Also confirmed in MPWMD Industrial Ponds Percolation and Evaporation Technical Memorandum 2015-01, July 2015.

10 Max. diversion = 6 cfs. See REVISED DRAFT RECLAMATION DITCH YIELD STUDY, Schaaf and Wheeler, March 2015. Note that flow figures shown here are a combination of flow estimates in the S&W analysis made for the 2 cfs instream requirement Jan-May and 1 cfs instream requirement for June-Dec.

11 Max. diversion = 3 cfs. See REVISED DRAFT RECLAMATION DITCH YIELD STUDY, Schaaf and Wheeler, March 2015. Figures shown here are the difference between the combined Davis Road/TS diversion with Seasonal Bypass. This presumes the preference is to remove flow at Davis Road first, rather than bypass flow to Tembaldero Slough.

12 Includes secondary effluent wastewater currently used to produce recycled water at the Salinas Valley Reclamation Project (SVRP), and additional amounts which may be used during periods of low demand (<5 mgd) with the proposed improvements to the SVRP.

13 New source waters not used by AWT will be available to SVRP for CSIP.

14 A drought reserve of up to 1,000 AF would be created over five years by producing 200 AFY additional product water from the GWR Project AWTF during winter months and storing the water in the Seaside Basin. This would establish a "water bank" that the CSIP can draw on in droughts. The drought reserve would allow flow at the RTP for the GWR Project to be temporarily reduced during critically dry periods, thus freeing up more of the newly available inflows to the RTP to be sent to the CSIP area. Extraction from the Seaside Basin would continue at the average rate to supply the Monterey Peninsula.

15 Average monthly RTP discharge, 2009-2013 (reported by MRWPCA).

16 Secondary treated municpal effluent not used for SVRP or the AWT.

17 Excess is calculated as Line 13 minus Lines 15 & 16

18 RUWAP supply comes from existing RTP inflows, demands reflect existing urban irrigation customers along trunk main.

**Table 7C: Source Water Analysis for the Pure Water Monterey Groundwater Replenishment Project**

**Notes**

1 Presumes all facilities associated with diversions are completed.

2 Table 2-1, p. 5, Schaaf & Wheeler Consulting Engineers. Revised Draft, Groundwater Replenishment Project, Salinas River Inflow Impacts, Prepared for Denise Duffy & Associates, February 2015.

3 Volume of effluent from City of Salinas agricultural wash water to be directed into ponds 1,2,3, and the aeration pond for storage.

4 Assume dry year at 1/3 the average monthly values from Revised Draft, Groundwater Replenishment Project, Salinas River Inflow Impacts, Prepared for Denise Duffy & Associates, February 2015.

5 Rainfall from Revised Draft, Groundwater Replenishment Project, Salinas River Inflow Impacts, Prepared for Denise Duffy & Associates, February 2015. Pond area presumed to be Ponds 1,2, 3 + Aeration lagoon. No rainfall/evaporation or storage assigned to drying beds.

6 Table 3, Todd Groundwater, Draft Memorandum, Pure Water Monterey Groundwater Replenishment Project: Impacts of Changes in Percolation at the Salinas Industrial Wastewater Treatment Facility on Groundwater and the Salinas River, February 11, 2015.

7 Table 4, Ibid.

8 Ponds 1,2,3 and aeration basin hold up to 1,065 acre-feet (one foot of freeboard). If flow to ponds would exceed the maximum volume, it is presumed that excess flow can be diverted to the RIBs or drying beds or flow can be diverted to the RTP. Presume that pond storage goes to zero sometime during the year (shown here starting in July).

9 Table 4, Ibid. Also confirmed in MPWMD Industrial Ponds Percolation and Evaporation Technical Memorandum 2015-01, July 2015.

10 Max. diversion = 6 cfs. See REVISED DRAFT RECLAMATION DITCH YIELD STUDY, Schaaf and Wheeler, March 2015. Note that flow figures shown here are a combination of flow estimates in the S&W analysis made for the 2 cfs instream requirement Jan-May and 1 cfs instream requirement for June-Dec.

11 Max. diversion = 3 cfs. See REVISED DRAFT RECLAMATION DITCH YIELD STUDY, Schaaf and Wheeler, March 2015. Figures shown here are the difference between the combined Davis Road/TS diversion with Seasonal Bypass. This presumes the preference is to remove flow at Davis Road first, rather than bypass flow to Tembaldero Slough.

12 Includes secondary effluent wastewater currently used to produce recycled water at the Salinas Valley Reclamation Project (SVRP), and additional amounts which may be used during periods of low demand (<5 mgd) with the proposed improvements to the SVRP.

13 New source waters not used by AWT will be available to SVRP for CSIP.

14 A drought reserve of up to 1,000 AF would be created over five years by producing 200 AFY additional product water from the GWR Project AWTF during winter months and storing the water in the Seaside Basin. This would establish a "water bank" that the CSIP can draw on in droughts. The drought reserve would allow flow at the RTP for the GWR Project to be temporarily reduced during critically dry periods, thus freeing up more of the newly available inflows to the RTP to be sent to the CSIP area. Extraction from the Seaside Basin would continue at the average rate to supply the Monterey Peninsula.

15 Monthly RTP discharge during critically dry year (2013), reported by MRWPCA

16 Secondary treated municpal effluent not used for SVRP or the AWT.

17 Excess is calculated as Line 13 minus Lines 15 & 16

18 RUWAP supply comes from existing RTP inflows, demands reflect existing urban irrigation customers along trunk main.

# TECHNICAL MEMORANDUM

**TO: Bob Holden, MRWPCA** **DATE: September 16, 2015**

**FROM: Andrew A. Sterbenz, PE; Andrew Racz, EIT** **JOB #: MRWP.01.14:004**

**SUBJECT: Fish Passage Analysis: Reclamation Ditch at San Jon Rd. and Gabilan Creek at Laurel Rd.**

---

**INTRODUCTION:**

This technical memo assesses hydraulic conditions through structures that may pose as obstacles to upstream and downstream anadramous fish migration in the Reclamation Dich/Gabilan Creek watershed. Two sites are analyzed: the Reclamation Ditch at the San Jon Road bridge/weir, and Gabilan Creek at the Laurel Road culvert. The purpose of the analysis is to determine (1) whether these structures pose obstacles to fish passage, and if so, under what range of flows, (2) whether withdrawals of up to 6 cfs from the Reclamation Ditch for the Pure Water Monterey Groundwater Replenishment Project will reduce the likelihood of fish passage between Monterey Bay and upstream habitat, and (3) if this is found to be the case, the range of flows at which withdrawals should be curtailed in order to maintain fish passage.

**SITE 1: RECLAMATION DITCH AT SAN JON ROAD**

The structure at San Jon Rd. is a single-span concrete bridge over a trapezoidal concrete-lined channel. The low chord of the bridge sits approximately 10’ above the channel bed, and channel’s cross section tapers from 40’ below the bridge deck to 12’ at its base. Flow through the culvert is further constricted by a flow gage (USGS 11152650) consisting of a rectangularly-notched concrete weir, dimenstions 8’ wide x 2’ high. There is a 0.6’ deep lip on the upstream side of the weir. On its downstream side, the weir discharges onto a concrete apron that widens from 8’ to 12’ and experiences a vertical drop of approximately 1.0’ over 20.5’ of flow distance. The apron discharges onto a riprap (12”-24” boulders) lined channel. Riprap extends approximately 24’ downstream, and the streambed elevation drops an additional 2.4’ over this distance. Downstream of the riprap, the channel bed transitions to deposited sediment, and the slope flattens significantly.

**FishXing Model:**

*FishXing v3.0* is a publicly available modeling program from the US Forest Service. The program allows the user to model flow through various stream/road crossing structures. It also allows the user to evaluate the ability of fish and other aquatic species to navigate these structures based on species-specific physiological parameters such as minimum required water depth, swimming speed and endurance. FishXing was initially used to calculate water surface profiles through the San Jon Road weir to determine what ranges of flows might allow for successful upstream passage of adult steelhead.

For adult steelhead, the following default species parameters were used:

- Length: 18"
- Prolonged Speed: 8 ft/s;
- Prolonged time to exhaustion: 10 min
- Burst Speed: 16 ft/s
- Burst time to exhaustion: 5 s
- Minimum depth: 0.5 ft
- Maximum leap speed: 16 ft/s

A simple model of flow throuh a 2' x 8' concrete channel representing the notch of the weir was created in FishXing. Results indicated that migrating steelhead could traverse the weir at flows between 45 – 150 cfs. At lower flow rates, water depth was insufficient to allow fish passage. At higher flow rates, high velocities resulted in fish exhaustion.

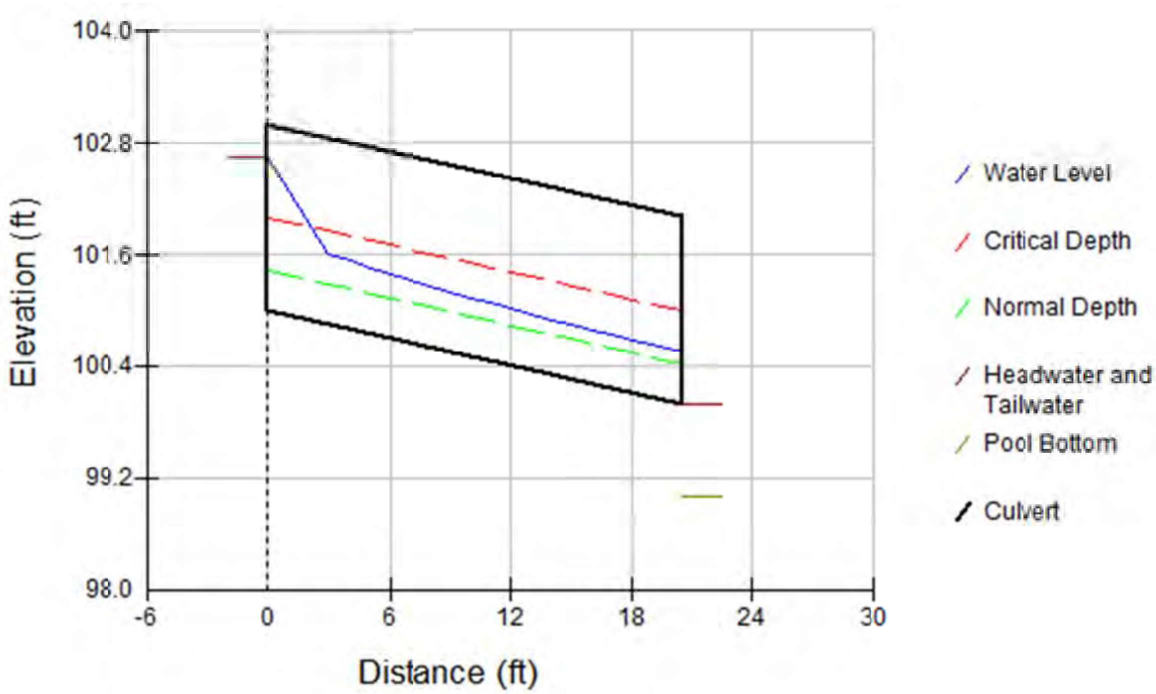

**Figure 1:** Water surface profile results for 45 cfs of flow through the rectangular weir at San Jon Road, generated by FishXing.

The FishXing model is an oversimplification of the San Jon Road weir geometry. This simple model depicts only the notch of the weir. It does not accurately depict flow behavior when backwater overtops the notch, nor does it consider how flow behavess downstream of the weir as it crosses over the concrete apron and riprap. Field observations have shown that, beginning at approximately 70 cfs, flow overtops the 2' high wall of the weir notch, and begins occupying the entire cross sectional width of the culvert (see Figure 2B). Thus, the upper bound for fish passage as calculated by FishXing (150 cfs) is not a reliable result. At lower flows, the shallowest water depths that impede upstream fish migration have been observed to occur not through the weir notch, but over the concrete apron. In short, the geometry of the San Jon Road structure is too complicated to model using FishXing. In the following section, we create a more detailed and reliable Hydrologic Engineering Centers River Analysis System (HEC-RAS) model to more precisely determine passage flows.

**HEC-RAS Model Design:**

The weir, apron and riprap were surveyed in the field, and individual cross sections representing these features' geometry and roughness were created in the model. The bridge over the weir/culvert was not modeled, as flow rates in question do not reach the height of the bridge deck's low chord. Cross sections approximately 500' upstream and downstream of the bridge were imported from the existing regional model of the Reclamation Ditch watershed. Bed slopes at these outlying cross sections were used to determine the model's boundary conditons using normal depth. Flow was modeled for 10 flow rates between 10 and 240 cfs (Table 1). For reference, the 10-year storm event at this location is >600 cfs (FEMA Flood Study).

**Model Results:**

***Weir***: At flow rates below approximately 70 cfs, all flow passes through the rectangular notch of the weir. When flows exceed this value, the weir is overtopped and flow occupies the entire channel width. This result is in line with field observations (see Figure 2B below).

***Apron***: In all cases, the concrete apron contains the point of shallowest flow. At flow rates below approximately 240 cfs, the shallowest flow is at the downstream lip of the apron. At higher flows, depth is shallowest immediately below the weir. Flow depth over the apron increases with flow rate, from a depth of about 2" at 10 cfs to >1' when flow exceeds approximately 160 cfs.

At all flow rates, flow velocity reaches its maximum at the downstream lip of the apron. Flow velocities at this location range from approximately 5 ft/s at Q=10 cfs, to >12 ft/s at Q=240 cfs. A cross-sectional profile of flow shows the fastest velocities along the centerline of the apron, where flow remains supercritical for all flow rates. Flow transitions to subcritical at the apron-riprap transition, as well as along the margins of the apron (see Figure 2 photos). As a result of this phenomenon, the apron never becomes fully sumberged by tailwater in the downstream channel, even at very high discharge rates.

***Riprap***: Flow transitions from supercritical to subcritical over the riprip-lined channel immediately downstream of the weir. This transition occurs closer to the apron at low flows and farther downstream at higher flows. At flow rates below approximately 150 cfs, the longitudinal water surface profile over the riprap is positive, and water cascades downstream over the riprap. At around 150 cfs, the water surface profile over the riprap is parallel to that of the tailwater. As flow rates increase to above 150 cfs, the hydraulic jump propogates downstream, and the water surface profile over the riprap tilts upstream toward the lip of the apron.

**Fish Passage Analysis:**

Typical flow values in the Reclamation Ditch are <5 cfs, with larger flows occurring during and after storm events. Because urban runoff comprises a significant portion of these larger flows, storm hydrographs on the Reclamation Ditch exhibit characteristically "flashy" behavior, with storm peaks typically only lasting from 12-48 hours. Flow depths cited by Hagar (Technical Memo, 2/28/15) for the passage of adult and juvenile salmonids (0.6' and 0.4' respectively) occur at corresponding discharges of approximately 75 and 40 cfs (Figures 3, 4, 6). For adult upstream migration, 75 cfs of flow corresponds to a flow velocity of 9 ft/s (Figure 5). Although this flow is too rapid for sustained upstream propulsion, high enough speeds can be achieved for short bursts (up to 5 seconds to clear the length of the approximately 40-foot obstacle. For the purposes of this study, we will assume that velocity does not pose a barrier to fish passage, and we will rely on minimum flows. In order to divert up to 6 cfs of flow while still maintaining the required 75 and 40 cfs instream, flow diversions could occur when flows are below 75 cfs or in excess of 81 cfs (adult migration season), and below 40 cfs or in excess of 46 cfs (juvenille migration).

**PART II: GABILAN CREEK AT LAUREL ROAD**

The only identified habitat in the Reclamation Ditch watershed suitable for steelhead spawning is the upper, undeveloped reach of Gabilan Creek in the hills north of Salinas. Gabilan Creek is a seasonal stream, flowing only after rain events and during wet winters and springs. Upon entering the city, Gabilan Creek passes through a series of bridges and culverts and is surrounded by mostly suburban and commercial development and some greenspace. This reach of the creek receives urban stormwater runoff from the surrounding area. Gabilan Creek's confluence with the Reclamation Ditch occurs in what is the bed of normally-dry Carr Lake in central Salinas, just downstream of a set of twin culverts beneath Laurel Road. Between Laurel Road and San Jon Road, all other road crossings are either bridges or low-slope box culverts that do not pose obstacles to fish passage. As a logical following to the San Jon Road weir analysis, we apply similar methods to examine flow requirements for fish passage through the Laurel Road culverts, the next possible upstream obstruction.

The structure at Laurel Rd. consists of two elliptical corrugated steel culverts, dimensions 7.5' x 10'. The culverts run a length of approximately 100' beneath Laurel Road, dropping 0.45' over this distance (average slope of 0.45%). The culverts discharge at-grade to a field of loosely spaced 12-24" riprap boulders that line the channel bed to approximately 24' downstream of the culvert outlet. The channel bed drops an additonal 2.4' over this distance. Downstream of the riprap, the channel bed transitions to coarse sand and the slope flattens significantly as it approaches the Carr Lake bed.

**Figure 7:** Image of the Laurel Road culverts, downstream end, on September 4, 2014.

**FishXing Model**:

Preliminary analysis using FishXing indicated upstream fish passage through the culverts might be possible between flows of 18 – 500 cfs. As was the case at the San Jon Road site, FishXing calculates flows through the culverts, but does not model the culverts and riprap/channel as a single system, and is thus of limited use. This is particularly true at this crossing, as maximum flow velocities and minimum flow depths occur not within the culverts, but over the riprap.

**HEC-RAS Model Design:**

The culverts and riprap-lined channel were surveyed in the field, and individual cross sections representing these features' geometry and roughness were created in the model. Cross sections approximately 2000' upstream and downstream of the bridge were modeled based on elevation and survey data from the 2009 FEMA Flood Insurance Study of Monterey County. Bed slopes at these outlying cross sections were used to determine the model's boundary conditons using normal depth. Flow was modeled for 16 flow rates between 10 and 1000 cfs (Table 2). For reference, the 10-year storm event at this location is 600 cfs (FEMA Flood Study).

**Model Results:**

***Culverts***: The twin culverts below Laurel Road have the capacity to accommodate flows in excess of 800 cfs before backwater fully submerges the culvert entrance. At all flow rates modeled, flow through the culverts remains subcritical, only transitioning to supercritical at the culvert outlet.

***Riprap***: When flow exits the culverts and begins flowing across the riprap, flow becomes supercritical, increasing in velocity and decreasing in depth. For all flow rates modeled, the maximum flow velocity and minimum flow depth is reached at the downstream limit of the riprap-lined channel, approximately 24' downstream of the culvert outlet. Flow depth over the riprap increases with flow rate, from a minimum depth of about 1" at 10 cfs to >2' when flow exceeds approximately 800 cfs. Flow velocities at this location range from approximately 5 ft/s at Q=10 cfs, to 17 ft/s at Q=1000 cfs.

**Fish Passage Analysis:**

Flow depths cited for the passage of adult and juvenile salmonids (0.6' and 0.4' respectively) occur at corresponding discharges of approximately 180 and 110 cfs (Figures 8, 9, 11). For adult upstream migration, 180 cfs of flow corresponds to a flow velocity of 11.5 ft/s (Figure 10). This value is too likely too rapid for sustained swimming, but may be acheivable for short bursts through the riprap field. FishXing indicated that should a fish succeed in entering the culvert, it could continue upstream without succombing to exhaustion so long as flows remained below approximately 500 cfs. For the purposes of this study, we will assume that velocity is not prohibitive to upstream fish passage.

During an approximately seven-year period from 2007 – 2014, the USGS maintained an operable gage (USGS 11152600) on Gabilan Creek at Old Stage Road, approximately 3.5 miles north of the Laurel Road crossing (see Figure 12). Flows at that location are sporadic, and were only recorded to exceed 180 cfs on one occasion in the record. Gabilan Creek watershed comprises approximately 40% of the Reclamation Ditch watershed upstream of San Jon Road. Out migration of smolts riding on storm flows should therefore not be hindered by a 6 cfs diversion at Davis Road, because a storm producinging 110 cfs at Laurel Drive would exceed 200 cfs at San Jon Road. Upstream migration of adults is more greatly restricted by conditions in Gabilan Creek than by conditions in the Reclamation Ditch. Fish passing San Jon Road and the Davis Road diversion point may still be stranded in Carr Lake awaiting sufficient flows to ascend Gabilan Creek. This is the existing condition in the system, and should not be affected by diversions so long as passage at the San Jon Road gage is accomodated.

| Flow rate (cfs) | HEC-RAS ID | Minimum flow depth (ft) | Maximum flow velocity (ft/s) |
|---|---|---|---|
| 10 | PF 1 | 0.09 | 4.7 |
| 20 | PF 2 | 0.14 | 6.2 |
| 30 | PF 3 | 0.18 | 7.2 |

# MEMORANDUM

| | | | |
|---|---|---|---|
| TO: | Bob Holden, MRWPCA | DATE: | August 10, 2015<br>Updated Sept. 23, 2015 |
| CC: | Alison Imamura, Denise Duffy & Assoc. | | |
| FROM: | Andrew Sterbenz, PE | JOB #: | MRWP.01.14 |
| SUBJECT: | Consideration of Water Right Application 32263 in the Pure Water Monterey Project EIR | | |

The Monterey County Water Resources Agency (MCWRA) submitted Water Rights Application No. 32263 on April 9, 2014 to the State Water Resources Control Board (SWRCB), for a diversion of up to 25,000 acre-feet per year (AFY) from the Reclamation Ditch/Tembladero Slough (RD/TS) and the Blanco Drain (combined total). On July 29, 2015, the MCWRA submitted Applications 32263A through 32263E, separating the request by diversion location and use. The purpose of this memorandum is to relate applications 32263A through 32263E to the Pure Water Monterey Project, identify discrepancies and discuss whether the revised applications need to be discussed in the final EIR.

The separate applications are listed in Table 1, below. Applications A, B and C are for the three surface water diversions for the Pure Water Monterey (PWM) Project. The PWM values are included in the table for comparison. The water right application values are the maximum annual diversions, while the PWM values are the average annual diversions, so the values for A, B and C align correctly with the values in the PWM DEIR. These applications refer to the yield studies included in the PWM DEIR as the basis for the water availability. Therefore, there is no inconsistency between applications A, B and C and the PWM DEIR.

**Table 1, Applications 32263A-E and PWM GWR Use**

| Application | Diversion Point | Amount (AFY)1 | Maximum Rate (cfs) | PWM (AFY)2 | PWM Max Rate (cfs) |
|---|---|---|---|---|---|
| 32263A | Blanco Drain | 3,000 | 6 | 2,620 | 6 |
| 32263B | RD at Davis Rd | 2,000 | 6 | 1,522 | 6 |
| 32263C | TS at Castroville | 1,500 | 3 | 1,135 | 3 |
| 32263D | Multiple3 | 9,800 | 30 | NA | |
| 32263E | Multiple3 | 8,700 | 55 | NA | |
| Total | | 25,000 | | 5,277 | |

1. Water Right application value is maximum annual diversion
2. DEIR value is average annual diversion
3. Includes all three diversion points from 32263A-C

Applications 32263D and E are for the remaining flows in the Reclamation Ditch/Tembladero Slough and the Blanco Drain. The estimation of total available flows in those streams was included as Attachment 3 to Application 32263D and as Attachment 1 to Application 32263E (same item, different sequential label). The estimates are shown in Table 2, below, in the column labeled MCWRA Estimate. These values reflect average year conditions. As can be seen, the average year available flow is less than the 25,000 AFY requested in the water rights applications, indicating that proposed water rights, if approved, would allow capturing all or most of the flows even during wet years. The MCWRA flow estimations contained several mathematical errors (addressed in a separate memorandum to MCWRA). The Revised Estimate column in Table 2 shows the corrected yields, using the methodology as explained in the applications. This methodology is slightly different than the methodology used by Schaaf & Wheeler in the water availability studies, so the results are similar but not equal.

**Table 2: Estimated Available Flows, Average Year Conditions**

| Source | MCWRA Estimate (AFY) | Revised Estimate (AFY) |
|---|---|---|
| Blanco Drain | 6,500 | 2,996 |
| RD/TS at Castroville | 15,937 | 10,064 |
| Total | 22,437 | 13,060 |

Making the correction above significantly reduces the estimation of flows available for water right applications 32263D and E. Additionally, not all of the existing flow in the Reclamation Ditch/Tembladero Slough system can be considered available for diversion. Several resource agencies (the Coastal Commission, the Central Coast RWQCB and NOAA NMFS) commented on the PWM DEIR that minimum flows must be maintained in the Reclamation Ditch and Tembladero Slough for steelhead migration and maintenance of wetland habitats. This does not preclude the diversion of peak storm flows when they occur, but would limit dry-season diversions under applications 32263D and E.

The PWM DEIR did not include a cumulative effects discussion of full use of water right application 32263 (25,000 AFY) because the original application did not provide any detail as to the place of use, the location and methods of diversion nor the need for storage reservoirs. It would have been purely speculative to discuss the portion of that water right application outside the PWM Project components. Item 3, Project Description, of Applications 32263D and E, both include the statement: “MCWRA has not yet defined a final project proposal but will be exploring options and conduct a feasibility study to determine the necessary course of action. A CEQA document would then be prepared for this project.” Based on those statements, there is still not enough information available to prepare a cumulative effect analysis for inclusion in the Final EIR.

SUBJECT: Consideration of Water Right Application 32263 in the Pure Water Monterey Project EIR

The Monterey County Water Resources Agency (MCWRA) submitted Water Rights Application No. 32263 on April 9, 2014 to the State Water Resources Control Board (SWRCB), for a diversion of up to 25,000 acre-feet per year (AFY) from the Reclamation Ditch/Tembladero Slough (RD/TS) and the Blanco Drain (combined total). On July 29, 2015, the MCWRA submitted Applications 32263A through 32263E, separating the request by diversion location and use. The purpose of this memorandum is to relate applications 32263A through 32263E to the Pure Water Monterey Project, identify discrepancies and discuss whether the revised applications need to be discussed in the final EIR.

The separate applications are listed in Table 1, below. Applications A, B and C are for the three surface water diversions for the Pure Water Monterey (PWM) Project. The PWM values are included in the table for comparison. The water right application values are the maximum annual diversions, while the PWM values are the average annual diversions, so the values for A, B and C align correctly with the values in the PWM DEIR. These applications refer to the yield studies included in the PWM DEIR as the basis for the water availability. Therefore, there is no inconsistency between applications A, B and C and the PWM DEIR.

**Table 1, Applications 32263A-E and PWM GWR Use**

| Application | Diversion Point | Amount (AFY)$_1$ | Maximum Rate (cfs) | PWM (AFY)$_2$ | PWM Max Rate (cfs) |
|---|---|---|---|---|---|
| 32263A | Blanco Drain | 3,000 | 6 | 2,620 | 6 |
| 32263B | RD at Davis Rd | 2,000 | 6 | 1,522 | 6 |
| 32263C | TS at Castroville | 1,500 | 3 | 1,135 | 3 |
| 32263D | Multiple$_3$ | 9,800 | 30 | NA | |
| 32263E | Multiple$_3$ | 8,700 | 55 | NA | |
| Total | | 25,000 | | 5,277 | |

1. Water Right application value is maximum annual diversion
2. DEIR value is average annual diversion
3. Includes all three diversion points from 32263A-C

Applications 32263D and E are for the remaining flows in the Reclamation Ditch/Tembladero Slough and the Blanco Drain. The estimation of total available flows in those streams was included as Attachment 3 to Application 32263D and as Attachment 1 to Application 32263E (same item, different sequential label). The estimates are shown in Table 2, below, in the column labeled MCWRA Estimate. These values reflect average year conditions. As can be seen, the average year available flow is less than the 25,000 AFY requested in the water rights applications, indicating that proposed water rights, if approved, would allow capturing all or most of the flows even during wet years. The MCWRA flow estimations contained several mathematical errors (addressed in a separate memorandum to MCWRA). The Revised Estimate column in Table 2 shows the corrected yields, using the methodology as explained in the applications. This methodology is slightly different than the methodology used by Schaaf & Wheeler in the water availability studies, so the results are similar but not equal.

**Table 2: Estimated Available Flows, Average Year Conditions**

| Source | MCWRA Estimate (AFY) | Revised Estimate (AFY) |
|---|---|---|
| Blanco Drain | 6,500 | 2,996 |
| RD/TS at Castroville | 15,937 | 10,064 |
| Total | 22,437 | 13,060 |

Making the correction above significantly reduces the estimation of flows available for water right applications 32263D and E. Additionally, not all of the existing flow in the Reclamation Ditch/Tembladero Slough system can be considered available for diversion. Several resource agencies (the Coastal Commission, the Central Coast RWQCB and NOAA NMFS) commented on the PWM DEIR that minimum flows must be maintained in the Reclamation Ditch and Tembladero Slough for steelhead migration and maintenance of wetland habitats. This does not preclude the diversion of peak storm flows when they occur, but would limit dry-season diversions under applications 32263D and E.

The PWM DEIR did not include a cumulative effects discussion of full use of water right application 32263 (25,000 AFY) because the original application did not provide any detail as to the place of use, the location and methods of diversion nor the need for storage reservoirs. It would have been purely speculative to discuss the portion of that water right application outside the PWM Project components. Item 3, Project Description, of Applications 32263D and E, both include the statement: “MCWRA has not yet defined a final project proposal but will be exploring options and conduct a feasibility study to determine the necessary course of action. A CEQA document would then be prepared for this project.” Based on those statements, there is still not enough information available to prepare a cumulative effect analysis for inclusion in the Final EIR.

# JAMES A. REYFF

Mr. Reyff is a Meteorologist with expertise in the areas of air quality and acoustics. His expertise includes meteorology, air quality emissions estimation, transportation/land use air quality studies, air quality field studies, greenhouse gas studies and environmental noise studies. He is familiar with federal, state and local air quality and noise regulations and has developed effective working relationships with many regulatory agencies.

During the past 26 years, Mr. Reyff has prepared Air Quality Technical Reports for over 20 major Caltrans highway projects and conducted over 200 air quality analyses for other land use development projects. These projects included microscale analyses, calculation of project emissions (e.g., ozone precursor pollutants, fine particulate matter, diesel particulate matter, and greenhouse gases), health risk assessments, and preparation of air quality conformity determinations. Mr. Reyff has advised decisions of federal and local air quality agencies regarding impact assessment methodologies and air quality conformity issues. He has conducted air quality evaluations for specific plans and General Plan updates and advised City and County staff on these topics.

Mr. Reyff has been responsible for a variety of meteorological and air quality field investigations in support of air permitting and compliance determinations. He has conducted air quality analyses of diesel generators in support of regulatory permitting requirements and environmental compliance issues. Mr. Reyff has designed and implemented meteorological and air quality monitoring programs throughout the Western United States including Alaska. Programs include field investigations to characterize baseline levels of air toxics in rural areas, as well as regulatory air quality and meteorological monitoring. He was the Meteorologist involved in a long-term monitoring program at the Port of Oakland that evaluated meteorological conditions and fine particulate matter concentrations in neighborhoods adjacent to the Port.

Mr. Reyff has conducted over 15 major acoustical technical studies for transportation systems. He has managed several research studies for Caltrans including a noise study that evaluated long-range diffraction and reflection of traffic noise from sound walls under different meteorological conditions. Mr. Reyff has also evaluated noise from power plants, quarries and other industrial facilities. He has also been actively involved in research regarding underwater sound effects from construction on fish and marine mammals.

# William M. Snider

Senior Fisheries Biologist

**Education**
Bachelor of Science, Fishery Sciences, University of California Davis, 1972

**HDR Tenure**
8 Years

**Industry Tenure**
40-plus Years

## *Professional Experience*

Mr. Snider has 40 years experience as a fishery biologist with an emphasis in stream habitat and fisheries assessments, stream habitat restoration, and fish-habitat relationships, as well as related regulatory and permitting requirements, including ESA consultation and water right procedures. Much of his experience is in development and application of methods to assess and ameliorate the effect of water development projects, stream flow allocations, habitat restoration, or related instream activities on fishery resources. His work has emphasized evaluating the life histories, population needs, and habitat requirements of federal- and state-listed anadromous and resident salmonids.

## *Project Experience*

**Monterey Regional Water Pollution Control Agency, Monterey Peninsula Groundwater Replenishment Project. -** Mr. Snider is the Consultant Team Lead for the fish impact assessment and environmental document preparation for the Monterey Peninsula Groundwater Replenishment Project. As technical lead, his responsibilities included identifying potential impact mechanisms and species to be evaluated, developing impact assessment methodologies, and evaluating operations-related impacts on aquatic species in the Salinas River.

**Carmel River Water Rights, Eastwood Project. –** Mr. Snider is the lead fishery biologist in an ongoing water rights proceeding addressing potential effects of changes in location and use of an existing water right on steelhead in the Carmel River.

**Santa Felicia Dam Fish Passage Project – United Water Conservation District**. Mr. Snider is the facilitator for a panel of experts in the fields of fishery biology and engineering that is developing and evaluating alternative fish passage and related restoration treatments for the Southern California Steelhead DPS pursuant to requirements of a NMFS biological opinion for the Santa Felicia FERC relicensing on the Santa Clara River, Ventura County. Mr. Snider brings over 35 years of experience concerning salmonid stream habitat needs, including evaluation of habitat needs in context of restoration options specific to local and population constraints and needs.

**US Forest Service, Steelhead Monitoring, Tracking and Reporting Program for Los Padres National Forest**. HDR is supporting the FS with their Steelhead Monitoring, Tracking, and Reporting Program (Program) for Los Padres NF, which is necessary to prevent irreparable harm to the species by ensuring the adverse impact to steelhead will not rise to the level of jeopardy, as defined under the federal ESA. HDR created a strategy to develop and implement a forest-wide steelhead trout population monitoring, tracking, and reporting program and to apply that strategy to define and implement the Program. Mr. Snider served as the technical lead in developing the steelhead monitoring plan.

**Merced River Hydroelectric Power Project– Merced Irrigation District**. Mr. Snider is the lead fishery biologist in an ongoing FERC Relicensing process assisting the Merced Irrigation District address a variety of fish and stream habitat issues on the Merced River. Mr. Snider is leading the effort to prepare a biological assessment pursuant to ESA Section 7 that addresses potential project effects on federal listed fish populations and designated critical habitat. He is also leading the Merced River Technical Advisory Committee that provides federal and state agencies and NGOs opportunity to discuss fishery and related management activities on the Merced River, including the Merced River Hydroelectric Project to acquire and apply information on habitat and fish populations to address protection, mitigation and restoration options for native and introduced fish species.

**Longfin Smelt Incidental Take Permit and CEQA Compliance—California Department of Water Resources**. Mr. Snider was the Project Manager and technical lead assisting DWR in obtaining an incidental take permit for longfin smelt, including preparation and processing of supporting CEQA documents, for the continued operation of the State Water Project. The project included development and application of an effects analysis to identify and evaluate SWP-associated take of longfin smelt as it relates to jeopardy of the longfin smelt populations to survive and recover.

**Lower American River Instream Flow Evaluation—California Department of Fish and Game.** Project Manager and Technical Lead of a long-term evaluation of the instream flow requirements for Chinook salmon, steelhead, and other fishes of the lower American River. Flow habitat relationships were evaluated using an IFIM approach that included collecting and processing data to compare fish habitat availability as a function of flow (PHABSIM) and evaluations to validate and calibrate these relationships by conducting a suite of studies on the relationships among the species life stage performance and habitat conditions primarily characterized by flow, temperature, channel morphology. Mr. Snider authored numerous technical reports presenting the results of these investigations that provided the foundation for the *American River Water Forum Aquatic Resources of the Lower American River: Baseline Report* (February 2001) and ultimately the draft flow management standard.

**Central Valley Chinook Salmon and Steelhead Recovery Plan—National Marine Fisheries Service.** Mr. Snider is assisting the National Marine Fisheries Service prepare a recovery plan addressing the Central Valley's three protected salmonid populations: winter-run Chinook salmon, spring-run Chinook salmon and steelhead. Preparation has involved conducting public workshops, development of a threats assessment and evaluation and identification of recovery actions to be considered for the Sacramento-San Joaquin Delta and its tributaries.

**Klamath Water Rights—Somach, Simmons and Dunn.** Mr. Snider is providing strategic assistance and technical support associated with the Klamath River Water Rights Adjudication. The cases involve: (1) the Klamath River instream flows required for anadromous salmonid passage between the Oregon-California border and Upper Klamath Lake; and (2) the upper Klamath Lake water surface elevations required for six target fish species, including Lost River sucker, shortnose sucker, Klamath largescale sucker, rainbow trout, and Coho and Chinook salmon.

**Instream Flow Program—California Department of Fish and Game.** Mr. Snider evaluated existing, and developed and assessed new, instream flow investigation procedures and conducted flow requirement investigations on streams throughout the state. He provided technical support to CDFG staff regarding instream flow evaluation methods and results. He initiated and led a coho salmon habitat needs investigation incorporating a variety of investigative tools to Coho populations situated at the two ends of their present range along the California coast. He also participated in a multi-agency team to assist Alameda County Superior Court reduce uncertainties surrounding the instream flow needs of salmon and steelhead in the lower American River. Mr. Snider was the project manager and technical lead for flow and habitat evaluations on the Carmel River (Monterey County), Brush Creek (Mendocino County), Lagunitas Creek (Marin County), Scott Creek (Santa Cruz County), Sacramento River (Keswick Dam to Red Bluff), Yuba River (lower Yuba County), lower Stanislaus River (Stanislaus County), Merced River (Merced County), Alameda Creek (Alameda

County), Truckee River and tributaries downstream of Lake Tahoe to Nevada Stateline, and all tributaries to Lake Tahoe.

**Coastal Lagoon Dynamics, and Aquatic Habitat Assessment—California Department of Transportation.** Mr. Snider is the Task Order Manager and Technical Lead for this Caltrans project. HDR is investigating the potential effects of bridge replacement on aquatic habitat in two coastal lagoons in Santa Cruz County. HDR is preparing a technical report to assist permitting and regulatory compliance requirements. The report will address the potential relationships between bridge design and lagoon dynamics as they relate to habitat requirements of species at risk within the Central California Coast.

**Lower American River Operations Group Member—California Department of Fish and Game**. Technical representative to the lower American River operation advisory group. Provided expertise involving fishery flow requirements in the lower American River to assist the Bureau of Reclamation identify real-time and short-term planning needs for instream fishery resources relative to current hydrological, reservoir storage, cold water pool, and fish population conditions.

**Lower American River Fish and Habitat Evaluations—Bureau of Reclamation and the U.S. Fish and Wildlife Service.** Project manager and technical lead of evaluations of flow fluctuation effects on anadromous and resident fishes, instream flow requirements, channel dynamics, and spawning gravel management and restoration under contract with the Bureau of Reclamation and the U.S. Fish and Wildlife Service. Authored technical reports addressing effect of flow fluctuation on rearing and spawning within the lower American River, quantity, quality, and distribution and use of salmonid spawning habitat in the lower American River.

**Lower American River EDF v EBMUD Special Master Technical Team Member—California Department of Fish and Game**. Technical representative to the fishery technical team established as a result of the Hodge Decision, the Superior Court decision addressing the fishery and other resource flow requirements in the lower American River relative to EBMUD entitlement to divert water from the Folsom Dam Complex. Mr. Snider was an expert witness for the Department of Fish and Game during the SWRCB hearing and then the EDF v EBMUD litigation in the Alameda County Superior Court. Project manager and technical lead for numerous, multi-year investigations of lower American River fishery resources, identified and overseen by the Special Master team, and under contract with the Sacramento County and EBMUD. Evaluations included Chinook salmon and steelhead spawning population and habitat evaluations, anadromous and resident rearing habitat requirements, and juvenile salmonid emigration.

**Coast-wide California Road Crossing and Fish Passage Survey and Evaluation—Caltrans.** Program Manager and Technical Lead. Prepared information to assist in development and application of protocols to assess fish passage for salmonids along California's coast.

**BDCP EIR/EIS—California Department of Water Resources.** Mr. Snider is the technical lead for analyses being conducted to identify effects of the Bay Delta Conservation Plan on fishery and aquatic resources within the San Francisco Bay Delta and its tributaries. The BDCP includes major changes in the operation of water facilities within the Delta and its tributaries, changes in water conveyance through the Delta, and extensive restoration of aquatic habitats within the rivers, bays, floodplains and other wetlands that adjoin the Delta and support unique and valuable fish and wildlife. The analyses will include development and application of various methods to address a suite of potential changes in habitat conditions on an assortment of listed fish species, including Delta and longfin smelt, Chinook salmon, steelhead, sturgeon and native minnows. Analyses will also address the influences of hydrology, hydrodynamics, and other stressors associated primarily with water development, on the ecosystems of the Delta, the estuary, and the tributary reservoirs and streams.

**Statewide Fish Passage Inventory—California Department of Transportation (Caltrans).** Mr. Snider is providing design guidance emphasizing a systematic approach to evaluation, selection, and design of the preferred fish passage solution that helps to streamline the environmental review and permitting processes. Additionally, HDR is providing technical support in the areas of hydrology, hydraulics, geomorphology, civil engineering, structural engineering, and technical writing.

**Stream Evaluation Program—California Department of Fish and Game.** Mr. Snider was the Senior Environmental Scientist and Supervisor responsible for managing the state of California's stream evaluation program to achieve its mission of developing, implementing, and applying flow and other habitat investigation methods to improve understanding of salmonid population and habitat needs.

**Environmental Staff Support—California Department of Transportation.** HDR currently holds an on-call contract to provide environmental support services to Caltrans through 2008. One of the current task orders includes support to the Caltrans Office of Biological Studies and Technical Assistance in developing policy, guidance, and documents. Mr. Snider oversees the environmental staff assigned to Caltrans.

**Environmental Documentation for Sacramento-San Joaquin Delta Assessments—U.S. Bureau of Reclamation.** Prepared environmental documents assessing the effects of the Environmental Water Account on the fisheries and aquatic ecosystem of the Sacramento-San Joaquin Delta and its tributaries. The assessments identified current conditions limiting fishery resources, including federally and state listed fish populations, including Chinook salmon, steelhead, green sturgeon, and delta smelt. Established and applied approaches to assess effects and integrated the findings into CEQA, NEPA and ESA required documents.

**Coho Programmatic Documents for Permitting Highway Maintenance Projects, California's North Coast—Caltrans.** Program Manager and Technical Lead. Developed information on effects and potential avoidance and mitigation measures regarding various effects of highway maintenance and construction on fish populations. The evaluated effects included noise and vibration, streambed alteration, water quality, and fish passage.

# Adrian E. Pitts

Northern California Fisheries Business Class Manager

**Education**
Bachelor of Science, Biology, University of California Davis, 1997

Master of Science, Conservation/Renew Nat Resrces, California State Univ Sac (Degree not complete)

**Professional Affiliations**
American Fisheries Society

**HDR Tenure**
12 Years

**Industry Tenure**
17 Years

## Professional Experience

Mr. Pitts is an aquatic scientist who specializes fisheries biology with specific emphasis on aquatic resources impact assessments. He has 15 years of experience in the areas of wetland delineation, aquatic bioassessment, terrestrial and aquatic special-status species habitat surveys, and terrestrial and fisheries impacts assessments. He has extensive knowledge of the California and federal regulatory environment, including the California Environmental Quality Act (CEQA), National Environmental Policy Act (NEPA), California and federal Endangered Species Acts (ESAs), and the Clean Water Act (CWA).

### *HDR Project Experience*

**Monterey Regional Water Pollution Control Agency, Pure Water Monterey Groundwater Replenishment Project.** Mr. Pitts is the project manager and quality control reviewer for the fish impact assessment and environmental document preparation for the Pure Water Monterey Groundwater Replenishment Project that proposes diverting surface water from several sources for groundwater replenishment. As the project manager, Mr. Pitts managed HDR's technical staff and coordinated project delivery with the client. As the quality control reviewer, Mr. Pitts supported HDR's technical lead in identifying potential impact mechanisms and species to be evaluated, developing impact assessment methodologies, and evaluating operations-related impacts on aquatic species in the Salinas River.

**Carmel River Water Rights, Eastwood-Odello Project.** Mr. Pitts is the project manager and quality control reviewer in an ongoing water rights proceeding addressing potential effects of changes in location and use of an existing water right on steelhead in the Carmel River. Mr. Pitts manages HDR's technical staff and coordinates project delivery with the client. In his technical role, Mr. Pitts supports developing impact assessment methodologies, and evaluating potential flow changes in the Carmel River.

**US Forest Service, Steelhead Monitoring, Tracking and Reporting Program for Los Padres National Forest**. HDR supported the Forest Service by leading the development of their Steelhead Monitoring, Tracking, and Reporting Program (Program) for Los Padres National Forest (LPNF), which was necessary to monitor LPNF activities and prevent irreparable harm to the species. HDR created a strategy to develop and implement a forest-wide steelhead population monitoring, tracking, and reporting program and to apply that strategy to define and implement the Program. Mr. Pitts served as the project manager for HDR and served as a senior scientist working closely with HDR's technical lead and Los Padres NF staff to develop the steelhead monitoring plan and present the proposed plan to the National Marine Fisheries Service and California Department of Fish and Wildlife

**California Department of Transportation, Statewide Fish Passage Inventory.** Mr. Pitts currently serves as a technical adviser to HDR's team that is conducting reconnaissance and detailed fish passage assessment field surveys along the highways of Santa Cruz, Marin, and San Mateo counties. Mr. Pitts also advises the HDR team on field safety protocols and procedures, data management, data analysis, and GIS activities.

**Merced River Hydroelectric Power Project– Merced Irrigation District**. Mr. Pitts serves as a senior scientist and endangered species advisor to HDR's team in an ongoing

FERC Relicensing process assisting the Merced Irrigation District address a variety of fish and stream habitat issues on the Merced River. Mr. Pitts served a lead role in preparing a biological assessment pursuant to ESA Section 7 that addresses potential project effects on federal listed fish populations and designated critical habitat. Additionally, Mr. Pitts served as a senior reviewer for development of study plans and study plan reports evaluating Merced River aquatic resources.

**USACE San Francisco District, South San Francisco Bay Shoreline Study**. Mr. Pitts served as the senior Quality Control reviewer for the the aquatic species analysis for a programmatic Environmental Impact Statement (EIS) and Biological Assessment (BA) for the San Francisco Corps of Engineers District's Shoreline Phase 1 Project. This project includes construction of new levees and berms, replacement and installation of in-stream structures, creation of new tidal salt marshes, importing and placement of dredged material, tidal wetland creation and restoration, and creation of recreation facilities in the San Francisco Bay. Fish species potentially affected by the project include state and federally listed estuarine and anadromous species including longfin smelt and the Central California Coast Distinct Population Segment of Steelhead.

**USACE Sacramento District – Folsom Water Control Manual Update**. HDR is supporting the USACE Sacramento District as they develop a new Water Control Manual for the safe and efficient operation of Folsom Dam after the construction of the Joint Federal Project auxiliary spillway. Doing so will require detailed analysis of impacts to seasonal storage variations and how those impacts affect water supply, power generation, and critical environmental factors such as temperature, sedimentation, water quality, etc. HDR's resource specialists will utilize existing hydrologic, hydraulic, water temperature, and water quality models, as well as develop, apply, and integrate, new models to evaluate the impacts of implementing the new water control manual. Mr. Pitts is serving as the fisheries technical lead. He and his team are developing new approaches to evaluating flow and water temperature-related impacts on steelhead and fall-run Chinook salmon in the lower American River.

**Yuba County Water Agency, Lower Yuba River Accord. Lower Yuba River Accord Environmental Impact Report/Environmental Impact Statement (EIR/EIS).** Mr. Pitts was part of the HDR team that provided environmental compliance services for the proposed Lower Yuba River Accord (Yuba Accord), comprised of a coalition of over 15 agricultural, environmental, and fisheries interests, including state and federal agencies. The proposed Yuba Accord is a collaborative settlement initiative, which proposes new instream flow requirements for the lower Yuba River that will significantly increase protection for the rivers fisheries resources and will improve habitat conditions for lower Yuba River Chinook salmon and steelhead. The proposed Yuba Accord also will represent the first major long-term water acquisition by the State of California for the CALFED Bay-Delta Program Environmental Water Account, and will improve water supply reliability for the major resource agencies. Mr. Pitts was responsible for and prepared the Terrestrial Resources chapter of the EIR/EIS.

**Yuba County Water Agency, River Management Team, Monitoring and Evaluation Program.** Following certification of the Yuba Accord EIR, on March 18, 2008, the State Water Resources Control Board approved a consensus-based, comprehensive program, known as the Lower Yuba River Accord (Yuba Accord). The Yuba Accord established a River Management Team (RMT), which includes representatives of YCWA, NMFS, USFWS, CDFG, PG&E, and NGOs. The RMT, through a consensus-based process, guides the expenditure of over $6 million through 2016, primarily for monitoring and evaluation of lower Yuba River fisheries and habitat. Mr. Pitts serves as HDR's project manager for the program and assists HDR's technical lead and support team. Recently, Mr. Pitts supported the development of the Monitoring and Evaluation (M&E) Program Interim Report that presented over five years of monitoring data and ultimately intends on determining whether implementation of the Yuba Accord is maintaining fish in good condition (consistent with Fish & Game Code § 5937) and achieving viable salmonid populations (VSP) (addressing NMFS recovery planning).

**California Department of Water Resources and US Bureau of Reclamation, North-of-Delta Offsite Storage (NODOS) Investigation.** Mr. Pitts served as HDR's project manager and the EIR/EIS Consultant Team Lead for the Fish and Aquatic Resources impact assessment and environmental document preparation for the North of Delta Offstream Storage (NODOS) Investigations Project conducted by DWR and the US Bureau of Reclamation. As HDR's lead author, his responsibilities included identifying potential impact mechanisms and species to be evaluated, developing impact assessment methodologies, and evaluating operations and construction-related impacts on aquatic species in the Sacramento River, Feather River, American River, and two intermittent creeks in the construction area. Building on his previous experience, Adrian's team refined and updated the tools they developed for the Bay Delta Conservation Plan EIR/EIS to further streamline the process of evaluating large amounts of empirical and modeled data, thereby saving time and money during the NODOS Investigations Project evaluation.

Mr. Pitts also participated on the multi-agency, multidisciplinary Environmental Coordination Advisory Team (ECAT) to identify resource agency concerns and act as a liaison between DWR and the California Department of Fish and Game, US Fish and Wildlife Service, and the National Marine Fisheries Service.

**California Department of Water Resources, Bay Delta Conservation Plan Environmental Studies.** Mr. Pitts served two major roles on the Environmental Impact Report/Environmental Impact Statement (EIR/EIS) consultant team. As the team lead for the Fish and Aquatic Resources impact assessment, his responsibilities included identifying species to be evaluated and issues of concern in the Sacramento-San Joaquin River Delta and its major tributaries. Additionally, Mr. Pitts led the team in researching and developing life history characterizations, developing impact assessment methodologies, and evaluating operations, construction, and restoration-related impacts on aquatic species. Adrian's team developed previously unused tools to conduct evaluations of large amounts of empirical and modeled data quickly, accurately, and cost effectively.

Prior to leading the Fish and Aquatic Resources team, Mr. Pitts led the consultant team's support of DWR's survey efforts. As the environmental survey lead, he worked closely with DWR senior staff and species experts to develop and implement a survey approach for special status birds, mammals, reptiles, amphibians, plants, and invertebrates, and to provide technical and administrative support to DWR survey teams.

**El Dorado Irrigation District, Environmental Assessment for Long-Term Warren Act Contract.** Mr. Pitts served as HDR's technical lead conducting analysis of potential water temperature and flow-related impacts on steelhead and fall-run Chinook salmon in an Environmental Assessment/FONSI for the U.S. Bureau of Reclamation to enter into a long-term (40-year) contract with the El Dorado Irrigation District (EID) to facilitate the delivery of up to 17,000 acre-feet per year non-Central Valley Project (CVP) water through Folsom Reservoir for municipal and industrial uses in the western portion of El Dorado County. The source of non-CVP water is EIDs direct diversion rights for waters of the South Fork American River at the Kyburz diversion dam, and rights for diversion to storage from Caples Lake in Alpine County, Silver Lake in Amador County, and Lake Aloha in El Dorado County, granted in Water Rights Permit 21112 by the State Water Resources Control Board (SWRCB). The water rights covered in Water Rights Permit 21112 are made available by the operation of existing facilities of Federal Energy Regulatory Commission El Dorado Hydroelectric Project No. 184 within the South Fork American River Basin.

**California Department of Water Resources and US Bureau of Reclamation, Yolo Bypass EIR/EIS.** HDR is initiating preparation of the planning and environmental documentation for NEPA/CEQA compliance for the Yolo Bypass Seasonal Floodplain Habitat Restoration and Fish Passage Improvements Project. Specific tasks include preparation of a Biological Assessment (BA), an Incidental Take Permit (ITP), and the EIR/EIS, as well as agency coordination and permitting support, as necessary. Mr. Pitts is currently serving as HDR's technical lead for fisheries and aquatic resources.

**Mammoth Community Water District, Mammoth Creek Environmental Impact Report.** Mr. Pitts was the project manager for preparation of the Mammoth Creek EIR, which addressed proposed changes in Mammoth Creek bypass flow requirements, management constraints, point of measurement, and place of use. Mr. Pitts led the HDR team to revise and update sections of a prior Draft EIR, which was issued in 2000. HDR was responsible for developing and applying an operations model for the Districts surface water diversions from Mammoth Creek.

As part of a collaborative effort led by the District, Mr. Pitts coordinated with key stakeholders including the Los Angeles Department of Water and Power, California Department of Fish and Game, California Trout, and the Town of Mammoth Lakes to ensure that their concerns were addressed in the EIR and to help gain consensus regarding many aspects of the project. Mr. Pitts also led HDRs internal team to provide support during the public scoping process and aid the District in developing the Proposed Project and Alternatives. Mr. Pitts participated in Mammoth Creek EIR Technical Committee meetings to assist in the development of the hydrologic operations model, identify data and existing studies for inclusion into the EIR, and to provide updates on the CEQA environmental process. Additionally, Mr. Pitts assisted with an analysis of 16 years of fish population survey data and authored a review of the Hot Creek Stressor Identification process, which identified trends in trout populations, including the relationship of trout abundance to flows, and evaluated the condition of Mammoth Creek benthic macroinvertebrates.

**California Department of Water Resources, Oroville Facilities FERC Relicensing.** Mr. Pitts provided technical, analytical, and agency consultation support services for the Federal Energy Regulation Commission (FERC) relicensing process for the hydroelectric facilities at Lake Oroville. He assisted in the preparation of environmental documentation required to support DWR's application for relicensing. Mr. Pitts prepared the aquatic resources sections of the Preliminary Draft Environmental Assessment (PDEA), including assisting in the development of the methodology for the aquatic resources analysis. He also assisted in the analysis of potential protection, mitigation, and enhancement measures related to aquatic resources, and evaluated issues associated with federally listed threatened and endangered fish species, and fish and wildlife agency Section 10(j) recommendations. The PDEA summarized and incorporated the analyses related to fish habitat, upstream passage, predation, and disease prepared by HDR during completion of the study plan reports for aquatic resources. r. Pitts contributed to the alternatives evaluation and the discussion of unavoidable adverse and cumulative effects.

Prior to his work on the PDEA, Mr. Pitts led an internal team in the development and implementation of fisheries resources and aquatic ecology study plans that were designed to analyze potential project effects on Feather River and Lake Oroville fish habitat, fish disease, fish passage, and fish predation. The study plans included tasks designed to investigate and evaluate anadromous fish habitat requirements, distribution of anadromous fish in the Feather River, resident fish habitat components, resident fish distribution, the feasibility of providing fish passage above Oroville Dam, fish interactions, and predation. In addition to his coordination role, Mr. Pitts responsibilities included authorship and implementation of the study plans, including performing relevant literature reviews, analyzing data, developing analysis strategies, conducting field studies, and drafting technical reports to satisfy the study plans. Mr. Pitts authored study plans for anadromous salmonids, specifically, spring-run Chinook salmon holding habitat characterization, steelhead spawning survey methodology, and steelhead rearing temperatures.

**Placer County Water Agency, Auburn Tunnel Outlet Modification Project.** HDR provided environmental services to support several phases of the Auburn Tunnel Outlet Modification Project for the Placer County Water Agency. The project involves improving the outlet structure for the Auburn Ravine tunnel to reduce the accumulation of fine sediments entering Auburn Ravine.

Mr. Pitts served as the project manager leading the HDR team to complete the environmental documentation under the California Environmental Quality Act and Endangered Species Act compliance documentation. Additionally, Mr. Pitts assisted with strategic planning to refine the design of the outlet structure and associated facilities, and provided support to the Placer County Water Agency during the environmental permitting process.

**Santa Clara Valley Water District, Anderson Dam Seismic Retrofit Planning and Environmental Consultant Services.** Assisted in the development and preparation of planning study documents, including the Problem Definition Report, Planning Study Report, and CEQA/NEPA documents, as well as permitting. The ultimate outcome of the planning services will be to recommend a preferred alternative to: resolve the seismic deficiencies in the dam embankment from the maximum creditable earthquake; resolve and remediate, if necessary, the outlet works for the potential fault rupture risk from a maximum creditable earthquake; and review and revise, as needed, the Probable Maximum Flood (PMF) and routing study to address possible deficiencies with the spillway.

**Santa Clara Valley Water District, Three Creeks Habitat Conservation Plan and Fisheries and Aquatic Habitat Collaborative Effort (FAHCE) EIR.** The Santa Clara Valley Water District is preparing a Habitat Conservation Plan (HCP) pursuant to a multi-stakeholder settlement agreement, the FAHCE Settlement Agreement. Mr. Pitts served as the project manager for the preparation of an Effects Assessment for the Three Creeks HCP, and as a senior scientist leading the evaluation of fisheries resources in the FAHCE Settlement Agreement EIR. The HCP was prepared to obtain incidental take authorization under the federal Endangered Species Act for ongoing water supply operations in three watersheds in Santa Clara County, CA. As the project manager for HDR, Mr. Pitts led the team that developed the effects assessment approach and conducted the effects assessment identifying the effects of water supply operations and conservation measures on Central California Coast steelhead. Mr. Pitts also is leading the team conducting operations modeling and evaluation of fisheries resources as part of the CEQA compliance process.

**Somach, Simmons & Dunn, Bear Canyon Creek Fish Passage Project.** Mr. Pitts was the project manager for the preparation of an EA/IS and Endangered Species Act compliance documentation for fish passage improvements and changes to reservoir operations on Bear Canyon Creek, located on the Rubicon (formerly Niebaum-Copola) Estate Winery in the Napa Valley.

As the project manager for HDR, Mr. Pitts coordinated with resource agency representatives, including the California Department of Fish and Game and the National Marine Fisheries Service, to facilitate collaboration among stakeholders and to support the project proponents in development of the passage facility design and reservoir operations plan. Additionally, Mr. Pitts led the HDR team that conducted analyses of potential environmental impacts associated with construction of the fish passage facilities and reservoir operations, including detailed analyses of potential effects on state and federally listed threatened and endangered species.

**Somach, Simmons & Dunn, Chico Ranch/Llano Seco Rancho Pumping Plant Maintenance of Channel Alignment River Mile 192.5 EA/IS.** Mr. Pitts served as the project manager for the preparation of an Environmental Assessment/Initial Study (EA/IS) and Action Specific Implementation Plan (ASIP) for the Rancho Llano Seco Channel

Alignment Temporary Maintenance Project on the Sacramento River. The project involved placement of longitudinal rock toe and tree revetment on the west bank, and removal of a debris island on the east bank of the Sacramento River near the confluence with Big Chico Creek.

Mr. Pitts managed the efforts of HDR staff to update an existing EA/IS and ASIP to address the potential environmental impacts associated with the project. Specifically, Mr. Pitts and the HDR team, in cooperation with the California Department of Fish and Game, U.S. Fish and Wildlife Service, and National Marine Fisheries Service, identified the analytical methodology and conducted the analyses to address potential impacts on fisheries terrestrial biological resources in and adjacent to the Sacramento River, including potential impacts on several state and federally listed threatened and endangered species. Mr. Pitts also led the team in the evaluation of non-biological resources in the EA/IS and diligently supported the project proponent and their attorneys to allow for the timely completion of the environmental permitting process. Construction of the M&T Ranch, Rancho Llano Seco Temporary Channel Maintenance Project was completed during November 2007.

**U.S. Bureau of Reclamation/Department of Water Resources/CDM, Action Specific Implementation Plan for the Environmental Water Account EIS/EIR.** Mr. Pitts assisted in the preparation of the Action Specific Implementation Plan, which must be approved by NMFS, USFWS and CDFG, to implement the Environmental Water Account. The EWA is one component of the long-term comprehensive plan adopted in the CALFED Bay-Delta Program Record of Decision. The overall purpose of the EWA is to increase water supply reliability and to provide sufficient protections, combined with the Ecosystem Restoration Program and the regulatory baseline, to address CALFED's ecosystem quality needs in the areas of fishery protection, restoration, and recovery. The ASIP is a document established by the CALFED Bay-Delta Program that will fulfill the requirements of, and initiate project-level compliance with, the federal and California ESAs and the Natural Community Conservation Planning Act. Tiering off the CALFED Multi-Species Conservation Strategy, Mr. Pitts assisted in preparation of environmental settings sections, specifically with regard to spring-run Chinook salmon analyses in Butte Creek. Mr. Pitts also prepared water quality settings for southern California reservoirs.

**Yuba County Water Agency, Biological Assessment for Yuba River Development Project Proposed License Amendment.** Mr. Pitts assisted in the preparation of the fisheries analyses for this project. YCWA is seeking to reduce flow fluctuations caused by emergency outages at the Narrows II Powerhouse by installing a synchronous full-flow bypass; reduced flow fluctuations would reduce stranding juvenile spring-run and steelhead and dewatering redds of these species. YCWA also is seeking to extend the flow reduction and fluctuation criteria to year-round to protect the steelhead/rainbow trout spawning life stage. Mr. Pitts analyzed the impacts of constructing the bypass on spring-run Chinook salmon and steelhead.

**Yuba County Water Agency, Deadwood Creek Monitoring Project**. Mr. Pitts assisted in the preparation of the final report for a six-year monitoring program for Deadwood Creek. Brown trout, rainbow trout, and benthic invertebrate populations were monitored, and substrate characterization was performed. The monitoring was conducted to determine whether the required minimum flows provide adequate protection for Deadwood Creek fisheries resources, and to evaluate long-term project-caused effects to Deadwood Creek trout populations.

**Yuba County Water Agency, Biological Assessment for Yuba River Development Project Proposed License Amendment.** Mr. Pitts assisted in the preparation of the fisheries analyses for this project. YCWA is seeking to reduce flow fluctuations caused by emergency outages at the Narrows II Powerhouse by installing a synchronous full-flow bypass; reduced flow fluctuations would reduce stranding juvenile spring-run and steelhead and dewatering redds of these species. YCWA also is seeking to extend the flow reduction and fluctuation criteria to year-round to protect the steelhead/rainbow trout spawning life stage. Mr. Pitts analyzed the impacts of constructing the bypass to spring-run Chinook salmon and steelhead, as well as the cumulative impacts to fisheries.

### *Non-HDR Project Experience*

**U.S. Forest Service, Eldorado National Forest, Section Dredge Monitoring.** Mr. Pitts led a team conducting a field investigation of the channel morphology and benthic invertebrate communities of five streams in the upper Cosumnes River Watershed. On each of the study reaches, affected areas were identified and mapped, and impacts to the physical habitat were recorded. Following protocols outlined in the California Stream Bioassessment Procedure, Mr. Pitts and his team then collected invertebrate samples from riffles upstream and downstream from affected sites on two of the streams. Upon completion of the laboratory analysis, Mr. Pitts analyzed the metrics produced by the laboratory in an attempt to determine if suction dredging had adverse effects on the benthic populations downstream from known mining claims within the study area.

Advanced Habitat Restoration Workshop for California Red-legged Frog (Elkhorn Slough Coastal Training Program)

California Red-legged Frog Workshop (Elkhorn Slough Coastal Training Program)

California Tiger Salamander Workshop (Elkhorn Slough Coastal Training Program)

Coastal Policy Workshop (Elkhorn Slough Coastal Training Program)

40-hour ACOE Wetland Delineation Training (co-taught course)
40-hour ACOE Advanced Wetland Delineation Training
Native Grass Identification (California Native Grass

Mr. Harwayne serves as the Natural Resources Division Project Manager and is the senior staff biologist for DD&A. In addition to directing biological data collection, analysis and documentation, Mr. Harwayne is responsible for development and management of new projects, document quality control, staff development, marketing development, contracting, and maintaining project budgets and schedules. With over 16 years of consulting experience, he brings to the firm the highest level of technical, analytical and management skills.

His technical capabilities are as follows:

- Initial Studies/Mitigated Negative Declarations (IS/MND)
- Environmental Assessments/Finding of No Significant Impact (EA/FONSI)
- Environmental Impact Reports (EIR)
- Environmental Impact Statements (EIS)
- Biological Assessments (BA)
- Natural Environment Studies (NES)
- Wetland Delineation Reports
- Wetland Banking Documents
- Mitigation Monitoring and Reporting Programs (MMRP)
- Habitat Conservation Plans (HCP)

- Expert botany, wildlife, and wetland science experience gained working on a wide variety of projects involving special-status species and sensitive habitats.

- Proficiency in conducting biological surveys, including protocol-level surveys for special-status wildlife and plant species such as the California tiger salamander, California red-legged frog, burrowing owl, sand gilia, Monterey spineflower, and seaside bird's beak.

- Experience working closely with resource and regulatory agencies in permitting projects of varying size and complexity, including:

    - California Department of Fish and Wildlife (DFW)
    - U.S. Fish and Wildlife Service (Service)
    - California Department of Transportation
    - Regional Water Quality Control Board
    - Army Corps of Engineers (ACOE)
    - California Coastal Commission

- Project Management with complex permitting processes, including Clean Water Act Sections 401 and 404, DFG 1602, federal Endangered Species Act Section 7 and 10 consultation and permit processes, State Endangered Species Act Section 2081 Incidental Take Permit, and fully protected species.

- Wetland delineations per ACOE and Coastal Act criteria and the design of wetland mitigation and restoration projects.

- Expertise in preparing scopes, managing subconsultants, and keeping projects within established budgets and timeframes.

- Regularly guest lectures on vernal pool ecology, wetland ecology, environmental regulatory requirements, and native plant identification at California State University Monterey Bay (CSUMB) and Monterey Peninsula Community College (MPC).

Association)

## Education

Bachelor of Science, Earth Systems Science & Policy (Marine and Coastal Ecology), California State University Monterey Bay, 2000

Continuing Education, Land Use/Natural Resources Topics, through University of California Extension Program and CLE International

## Experience

*Environmental Scientist/Planner/ Project Manager,* DD&A

*Research Assistant,* Monterey Bay National Marine Sanctuary

## Professional Affiliations

Member, Association for Environmental Professionals
Member, American Planning Association
Member, California Native Plant Society

## Registrations/Certifications

American Institute of Certified Planners (AICP)
CEQA and NEPA Intensive Workshop Certifications
Fairy and Tadpole Shrimp Identification Class and Service Test Certification
PADI Certified SCUBA Diver
Service Federal Recovery Permit No. TE-091857-0 - California tiger salamander
DFG Research Permit for Listed Plant Species No. 04-08-RP - Sand gilia
DFG Scientific Collection Permit No. CS-007722 - Aquatic invertebrates

With over 15 years at DD&A, Erin Harwayne, AICP, has managed and prepared numerous environmental documents in compliance with CEQA and NEPA for a wide variety of projects involving educational facilities, natural resources management, water supply and distribution, military base reuse, public works, and transportation and transit infrastructure. She has experience preparing all types and levels of environmental documents, including:

- Initial Studies/Mitigated Negative Declarations (IS/MND)
- Environmental Assessments/Finding of No Significant Impact (EA/FONSI)
- Environmental Impact Reports (EIR)
- Environmental Impact Statements (EIS)
- Biological Assessments (BA)
- Natural Environment Studies (NES)
- Wetland Delineation Reports
- Mitigation Monitoring and Reporting Programs (MMRPs)

Integrating her extensive background in ecology with land use planning, Ms. Harwayne utilizes an innovative approach toward solving complex environmental issues.

Her technical capabilities are as follows:

- Adeptness in regulatory permitting processes, including Clean Water Act Section 401 and 404, California Department of Fish and Wildlife (DFW) 1602 Lake and Stream Alteration Program, Federal Endangered Species Act Section 7 consultation and Section 10 permit processes, California Endangered Species Act Section 2081 Incidental Take Permits, and Coastal Development Permits.
- Management and preparation of environmental documents in accordance with CEQA and NEPA requirements and local, state, and federal policies and regulations
- Proficiency in conducting biological surveys, including protocol-level surveys for special-status wildlife and plant species such as the San Joaquin kit fox, California tiger salamander, black legless lizard, California red-legged frog, vernal pool crustaceans (fairy and tadpole shrimp), sand gilia, Monterey spineflower, and seaside bird's beak
- Experience in conducting wetland delineations per United States Army Corps of Engineers (ACOE) and California Coastal Act criteria
- Expertise in the environmental review processes for the California State University and University of California systems
- Excellent communication and presentation skills
- Highly skilled in technical writing and editing
- Expertise in preparing scopes, managing sub-consultants, and keeping projects within established budgets and timeframes

**Project Experience:**

ESRI User Conference
Navigating the Environmental Compliance Process in Coastal California, Elkhorn Slough Workshop

Mr. Johnson has 14 years of experience working in the environmental field as an Associate Environmental Scientist, with a background in environmental science and policy. During his tenure at DD&A Mr. Johnson has also served as the manager of the Geographic Information Systems (GIS) department. At DD&A his responsibilities include project management, rare plant surveys, protocol-level wildlife surveys, biological monitoring, and wetland delineations; preparation of biological reports, Mitigation Monitoring and Restoration Plans, CEQA documents and regulatory permit applications; Global Positioning System (GPS) data collection; Geographic Information Systems (GIS) analysis; and graphics support for biological and planning documents. Mr. Johnson holds state and federal permits to handle multiple listed wildlife species and is expert in conducting protocol presence/absence surveys for California red-legged for, California tiger salamander, and additional wildlife species.

He has experience in several GIS software platforms and their application to land planning policy and regulation. He has also worked with a variety of GIS datasets from several different agencies including; USGS, CCC, SPOT, MBARI, Digital Globe, several counties and cities, and several universities in the California State system.

His technical expertise is demonstrated in his background projects and training:

- Experience working closely with resource and regulatory agencies in permitting projects of varying size and complexity, including:
  - California Department of Fish and Wildlife (DFW)
  - U.S. Fish and Wildlife Service (Service)
  - National Marine Fisheries Service (NOAA Fisheries)
  - Army Corps of Engineers (ACOE)
  - California Department of Transportation
  - Regional Water Quality Control Board
- Extensive experience conducting biological monitoring, pre-construction wildlife surveys on a variety of projects, and biological trainings to inform construction crews and other project team members of the sensitive resources present within project sites and the protection measures afforded to them.
- Proficiency in conducting biological surveys, including protocol-level surveys for special-status wildlife and plant species such as the California tiger salamander, California red-legged frog, sand gilia, Monterey spineflower, and seaside bird’s beak.
- Technical experience includes preparing biological reports for a broad range of environmental documentation in accordance with CEQA and NEPA requirements and local, State, and federal policies and regulations, including the Clean Water Act and the federal and state Endangered Species Acts, including:
  - Biological Assessments (BA)
  - Natural Environment Studies (NES)
  - Wetland Delineation Reports
  - Mitigation Monitoring and Reporting Programs (MMRP)
  - Permit Applications for CDFG, ACOE, USFWS, etc.
- Botany, wildlife, and wetland science experience gained working on a wide variety of projects involving special-status species and sensitive habitats.

TODD GROUNDWATER

# Phyllis Stanin, PG, CEG, CHG

Vice President and Principal Geologist

**EDUCATION**

MS, Environmental Management, Hydrogeology thesis, University of San Francisco
BS, Geology, University of North Carolina

**REGISTRATIONS**

Professional Geologist California, No. 5311
Certified Engineering Geologist California, No. 1899
Certified Hydrogeologist California, No. 482
Registered Geologist Arizona, No. 45605

## PROFESSIONAL SUMMARY

Phyllis Stanin has been a professional geologist for more than 35 years with expertise in hydrogeology and groundwater basin management, and a particular emphasis on managed aquifer recharge (MAR) and conjunctive use. She also has experience with groundwater resource development including production and injection wells, geophysical applications, aquifer testing, and monitoring. She has conducted numerous regional hydrogeologic assessments using advanced analytical and numerical modeling tools. Her expertise also includes fate and transport of contaminants in groundwater including constituents of emerging concern. She has performed geologic investigations in seven states across the U.S. and conducted independent research on impacts to groundwater flow from geologic faults. Groundwater projects demonstrating the variety of her experience are described below.

### Managed Aquifer Recharge (MAR)

*Groundwater Banking and Groundwater Model Construction, Kern County CA*
Ms. Stanin is Project Manager for an evaluation of groundwater banking operations in Kern County, California. This ongoing project involves the development of a regional groundwater flow model to assess the effects of the groundwater banking projects on the Kern Fan. The MODFLOW groundwater model covers a 430 square mile area, and comprises a three-layer aquifer system using over 1 million model cells. Calibration to dynamic flow conditions over the period 1986-2010 was completed in 2013; as of 2015, a revised model calibration is underway.

*Aquifer Characterization and Recharge Feasibility Study, City of Modesto, Stanislaus County, CA*

Ms. Stanin is the project manager for an ongoing groundwater study for the City of Modesto. The project is the first step in the City's Managed Aquifer Recharge (MAR) Program to develop strategies for recharge of treated surface water for subsequent recovery. For part of the recharge analysis, Todd Groundwater is modifying and applying the USGS MERSTAN model, a regional groundwater flow model developed by USGS using the One-Water Hydrologic Model code. This is one of the first groundwater models constructed in this platform, which incorporates numerous modules for the improved simulation of surface water-groundwater interaction.

*Groundwater Replenishment Project, Monterey Regional Water Pollution Control Agency (MRWPCA), Monterey County, CA*

Ms. Stanin has served as the project manager and lead hydrogeologist on this project, which involves planned recharge of highly treated recycled water into the Seaside Groundwater Basin. Detailed hydrogeologic assessments have been completed over several years including the evaluation of target aquifers, recharge methods, and injection and recovery sites. Todd Groundwater also completed a preliminary design for vadose zone wells to recharge the shallow aquifer and deep injection wells for replenishment of the deeper aquifer. The conceptual design was completed with the application of a steady state numerical model constructed by Todd Groundwater. Ms. Stanin has worked with the Division of Drinking Water (DDW) on project design and the monitoring well program. CEQA compliance is underway with the preparation of an EIR with MRWPCA as the lead agency; Ms. Stanin is also providing technical support for the EIR (2008 – 2015).

*Recharge Optimization Studies, Rancho California Water District, Riverside County, CA*

Ms. Stanin was Project Manager of two studies to optimize recharge basin percolation for the Rancho California Water District in Riverside County. The studies were conducted on the Lower *Valle De Los Caballos* (VDC) and Upper VDC recharge basins. The Lower VDC project involved a field investigation of percolation basin properties, vadose zone testing and impacts of groundwater elevations on percolation. A hydrogeologic conceptual model and local-scale groundwater model were used to optimize the amount of water that could be recharged under varying groundwater conditions. The Upper VDC project also involved the construction and application of a local-scale model to optimize recharge over 110 acres of basins. The fate of recharge water including downgradient and vertical transport was modeled to determine the amount of recharge being captured by local wells. Various optimization strategies were modeled to balance short-term treatment objectives with long-term storage. The project also involved the recommendation of a well maintenance program and meetings with regulators from the Department of Public Health on the District's permit (2009 – 2012).

*Hydrogeologic Investigation of Recharge Potential, Western Municipal Water District, Riverside County, CA*

Ms. Stanin served as Project Manager for a hydrogeologic investigation to evaluate the potential for recharge at five sites in the Arlington Basin for Western Municipal Water District. Sites were evaluated for the enhancement of groundwater recharge with stormwater, recycled water, and/or imported water. The project involved the design and implementation of a field program to assess lithology, textures, infiltration rates, hydraulic and geotechnical properties of the vadose zone beneath the sites. Analytical modeling was conducted to examine mounding and transmitting capacities. Subsequently, two sites have been selected for additional investigation and preliminary design (2011 – 2012).

*Edwards Aquifer Optimization Study, Edwards Aquifer Authority, San Antonio, TX*
Ms. Stanin was project manager and lead hydrogeologist for a multi-year study of enhanced recharge strategies within this extensive karst aquifer system. The study applied a five-county MODFLOW groundwater model developed by the USGS to evaluate volumes and sources of potential recharge, wellfield siting and design for recovery, and the potential for recirculating water through the aquifer to increase residence time in the aquifer (2006 – 2009).

*Recharge Feasibility and Salt Loading Studies, City of Corona, Riverside County, CA*
Ms. Stanin has provided hydrogeologic support to the City on a variety of projects. In a recharge feasibility study, she directed a hydrogeologic investigation of a property in the city, which has been identified by the city and Western Municipal Water District as a potential recharge site for imported water. The investigation involved soil borings, laboratory analyses, and single-ring infiltrometer testing. Groundwater modeling was conducted to assess potential mounding and groundwater response to various enhanced recharge scenarios. In a separate project, she also served as Technical Director for an evaluation of salt loading associated with potential recharge projects involving imported water. This study combined details of the basin water budget with sources and sinks of total dissolved solids (TDS) and nitrate in the Temescal Groundwater Basin in Riverside County. The project incorporated an organized approach to the analysis developed by the Santa Ana Regional Watershed Protection Agency (SAWPA) and the Regional Water Quality Control Board. TDS modeling indicated that, while salt loading would increase on a mass basis, the lower concentrations of TDS in imported water would be beneficial overall to TDS levels in groundwater (2009 – 2010).

*Hayfield Groundwater Storage Project, Metropolitan Water District of Southern California, Riverside County, CA*
As Project Manager for Todd Groundwater, Ms. Stanin directed several phases of the Hayfield Groundwater Basin Storage project for Metropolitan Water District. The storage project involved recharge of excess Colorado River water into the basin for subsequent recovery. Initial projects focused on planning and facilities feasibility studies. In order to develop a hydrogeologic conceptual model of the undeveloped basin, Ms. Stanin designed and implemented an exploratory borehole and test well program, involving installation of 9 test wells and two monitoring wells, geophysical and flow logging, aquifer testing, and groundwater sampling. Ms. Stanin conducted the hydrogeologic assessment of the field program results and was able to identify areas for optimized recovery of banked Colorado River water (2002 – 2004).

**Groundwater Basin Management Plans (GWMP)**

*Groundwater Management Plan, Kern Delta Water District, Kern County, CA*

Ms. Stanin has assisted the Kern Delta Water District with a variety of groundwater support services. Recently, she was the project manager and primary author of the District's Groundwater Management Plan Update. The project involved a re-assessment of aquifers, development of a water budget, and documentation of numerous conjunctive use activities including a formal groundwater banking project with the Metropolitan Water District of Southern California and other water agencies. The plan was adopted in September 2013.

*Groundwater Management Plan, City of Corona, Riverside County, CA*

For the last 10 years, Ms. Stanin has assisted the City of Corona with a variety of groundwater projects. She was the primary author of the City's first GWMP. The City relies on groundwater for about one-half of the total water supply and had experienced declining water levels in some portions of their service area. The plan involved original geologic mapping and delineation of the City's most productive aquifers, characterization of groundwater quality, and development of a groundwater balance. She also served as Project Manager for the construction and application of a MODFLOW groundwater flow model, which was applied to evaluate various management strategies of managed aquifer recharge. The results of the analysis was that the basin could be sustainably managed with a variety of conjunctive use strategies. The final Groundwater Management Plan was adopted in 2008.

*Groundwater Management Plan, Wheeler Ridge-Maricopa Water Storage District (WRMWSD), Kern County, CA*

Ms. Stanin assisted WRMWSD with the preparation of the District's first GWMP. The plan included a District-wide assessment of recent and historical water levels and groundwater quality. The plan included an analysis of the District's contract for the State Water Project and various Kern County banking programs in which the District had invested. The analysis recommended conditions under which surface water, banked water, or groundwater would be prioritized for use. The plan was adopted in November 2007.

*Development of Basin-Wide Monitoring Plan, San Benito County Water District (SBCWD), CA*

Ms. Stanin was Project Manager for the development of a basin-wide water quality monitoring program for SBCWD. The project involved the development of a GIS-compatible database of current and historical water quality data from more than 50 water systems, more than 30 facilities with groundwater monitoring, and other state and local agencies. The database and GIS are being used to assess current and historical water quality conditions in the basin. The results of the water quality assessment also are being used to optimize groundwater management activities and monitoring in the basin. The program was funded by an AB303 grant, which was obtained through a joint effort by the SBCWD and Todd Groundwater (2002 – 2004).

**Groundwater Resource Development**

*Groundwater Exploration Studies, City of Corona, Riverside County, CA*

Over the last decade, Ms. Stanin has provided hydrogeologic support to the City on a variety of projects. Recently, she served as Project Manager and Lead Hydrogeologist for an exploratory borehole/monitoring well program to identify favorable areas for future water supply wells for the City of Corona. The project involved the design and implementation of a field program to drill six boreholes and install five monitoring wells to delineate aquifer units in areas of limited groundwater data. The successful drilling and testing program included geologic and geophysical logging, aquifer thickness and elevation mapping, water level monitoring and mapping, water quality sampling and analysis, and isotopic and geochemical analyses. The study produces target areas for water supply wells and recommendations on well design (2012 – 2013).

*Groundwater Development for Ecosystem Restoration, California Department of Fish and Game, Camp Cady, San Bernardino County, CA*

Ms. Stanin was project manager for a groundwater investigation at Camp Cady, on the Mojave River, east of Barstow, CA. The goal of the project was to determine if damaged riparian vegetation that previously supported a thriving ecosystem could be restored by groundwater irrigation. Declines in shallow groundwater levels, among other factors, had eliminated vegetation in some areas. To evaluate if deep pumping could provide supplemental supply during critical dry times without lowering shallow water levels, a series of 11 shallow piezometers and four monitoring well clusters were installed. Project results indicated that groundwater pumping below the regional aquitard was feasible in favorable areas with careful planning. Recommended locations, well design, and project costs were also provided (2011 – 2013).

*Hayfield Groundwater Storage Project, Metropolitan Water District of Southern California, Riverside County, CA*

Ms. Stanin served as Project Manager for the design, drilling, installation, and testing of a large-diameter production well to recover stored water in the western portion of the groundwater basin. The project resulted in a high-yielding well producing 3,000 gpm with less than 30 feet of drawdown (2009 – 2010).

*Well 231 Replacement Project, Rancho California Water District, Riverside County, CA*

Ms. Stanin is currently serving as Principal-in-Charge for an evaluation of groundwater quality conditions in the Lower Pauba Valley to site a replacement municipal production well. The District has lost production recently due to elevated total dissolved solids (TDS), arsenic and fluoride concentrations. Todd Groundwater has identified stratigraphic intervals associated with some of the elevated constituents and is preparing a Preliminary Design Report to target specific aquifer zones for development. Todd Groundwater is also designing a test well to evaluate the vertical distribution of certain constituents in more detail. That well will serve as a future monitoring well for the replacement production well (2014 – 2015).

*Groundwater Characterization of Mining Dewatering and Bedrock Wells, Idaho Maryland Mining Corp. (IMMC), Grass Valley, Nevada County, CA*

Ms. Stanin served as the Project Manager and lead hydrogeologist for an evaluation of dewatering impacts from the Idaho Maryland Mine in Nevada County, CA. The IMMC had planned to re-open the previously-abandoned mine for additional gold mining operations.

Todd Groundwater provided hydrogeologic support to IMMC including an assessment of groundwater conditions and potential impacts from dewatering of mine workings on local bedrock wells. The assessment supported the preliminary dewatering design and provided an impacts analysis for the project EIR (2006 – 2011).

*Depth-Specific Monitoring and Aquifer Characterization, San Benito County Water District*
Ms. Stanin served as Project Manager for an aquifer characterization analysis including the installation and testing of a deep nested monitoring well in the Gilroy-Hollister Groundwater Basin. The well was needed to characterize the vertical distribution of boron and other constituents of concern with depth to identify future development areas. Todd Groundwater designed, installed, and tested a 770-foot nested monitoring well with five depth-discrete intervals. Depth-specific sampling and advanced geophysical logging, including a combined magnetic resonance tool, allowed for the identification of depths to avoid for future development based on elevated boron concentrations (2005 – 2007).

*Groundwater Characterization and Modeling, City and County of Honolulu, Oahu, HI*
Ms. Stanin was the Project Manager and lead hydrogeologist for the City and County of Honolulu Hawaii's well optimization program. This study included the evaluation of the aquifer system, a regional water balance, and detailed spatial and temporal correlation of groundwater pumping and upconing in water supply wells. The project also involved development of a 3-D numerical groundwater model to be used as an ongoing management tool by the Board of Water Supply (2004 – 2006).

*City of Dallas, Long-Range Water Supply Plan (LRWSP), Dallas Water Utilities, Dallas, TX*
As a subconsultant to HDR Engineering, Ms. Stanin served as project manager and lead hydrogeologist for a regional groundwater assessment. Although the City had historically relied exclusively on surface water reservoirs for water supply, options for supplemental groundwater supplies were evaluated as part of the LRWSP. The evaluation involved major and minor aquifers in a 13-county area of northeast Texas. Development strategies were analyzed by updating and applying the Water Availability Models (WAMs), consisting of two MODFLOW groundwater flow models developed by the Texas Water Development Board. Strategies included pumping groundwater for direct use, conveyance to surface water reservoirs, and non-potable use of shallow groundwater beneath the City (2012 – 2015).

**Regional Hydrogeologic Characterization**

*Groundwater Basin Conceptual Model, Bighorn-Desert View Water Agency and Mojave Water Agency, San Bernardino County, CA*
Ms. Stanin was project manager for development of regional hydrogeologic conceptual models and assessment of the feasibility of a managed aquifer recharge (MAR) project for three high desert basins. Hydrogeologic data were used to estimate groundwater storage and identify areas with coarse-grained lithology and favorable groundwater quality. Water levels were mapped across the basins with a particular emphasis on impacts from faulting or shallow bedrock. The study found that the Ames Valley basin would benefit most from a MAR project, given the occurrence of coarse-grained sediments beneath two major washes downgradient of geologic faults (2006 – 2007).

*Groundwater Basin Conceptual Model, Baja and Centro Subareas, Mojave River Groundwater Basin, Mojave Water Agency, San Bernardino County, CA*

Ms. Stanin was project manager for a multi-year study of two subareas comprising over 2,000 acres in the lower portion of the adjudicated Mojave River Groundwater Basin. The project included synthesized findings from historical studies dating back to early 1900s with analyses of new geologic, groundwater level and water quality data into one comprehensive document, which will be used to support future groundwater management planning, including managed aquifer recharge of imported State Water Project water. The project included conceptual and numerical groundwater flow model development and review; characterization of basin geometry, aquifer properties, impacts of hydraulic (fault) barriers on groundwater flow, groundwater water level trend analysis, evaluation of impacts of local and regional pumping and dam construction on surface water flows and downstream recharge along Mojave River; transient basin subarea water balance development; MODFLOW model water budget extraction and review; groundwater quality characterization; and water demand forecasting (2010 – 2013).

**Groundwater Support to Environmental Impact Reports (EIR)**

*Division of Oil, Gas, and Geothermal Resources (DOGGR) SB 4 EIR, Analysis of Oil and Gas Well Stimulation Treatments in California*

As a subconsultant to Aspen Environmental Group, Ms. Stanin led the Todd Groundwater analysis of groundwater impacts from well stimulation (including hydraulic fracturing) for the state-wide programmatic EIR. Working with DOGGR as the lead agency, Ms. Stanin developed a methodology for describing the environmental setting and impacts analysis of California groundwater from well stimulation including development and application of significance criteria. She also assisted with the development of project standards and alternatives. The DEIR was released in January 2015.

*Kern River Water Allocation Plan (WAP) EIR, Kern Delta Water District, Kern County, CA*

As a subconsultant to ESA Water, Ms. Stanin led the analysis of groundwater impacts from implementation of the District's Kern River WAP. The WAP consisted of a series of prioritized management actions for the full use of the District's entitlement to river water for irrigation and recharge in spreading basins. The EIR project involved a detailed assessment of river diversions and use over an 11-year study period and potential impacts to groundwater when other parties replaced previously-released river water with groundwater. The impacts analysis focused on water levels and water budgets north and south of the Kern River. As of 2015, a supplemental EIR is in preparation.

**Contaminant Hydrogeology and Groundwater Quality Studies**

*South Basin Groundwater Protection Project for Orange County Water District, CA*

Ms. Stanin directed this assessment of impacts to water supply wells from perchlorate and volatile organic compounds (VOCs). Data from 55 potential contaminant sources within a 1.5 mile radius of the wells were incorporated into the analysis. The evaluation also included a regional assessment, documenting groundwater flow directions from the 1950s to the present as pumping patterns changed throughout the groundwater basin. Capture zones were analyzed for impacted wells. An analysis of inorganic water quality data and pumping data revealed that contaminant concentrations went up during non-pumping conditions and co-varied with key inorganic constituents in shallow groundwater. These data led to a preliminary assessment of contaminant migration pathways and identification of key data gaps. A workplan was developed to address data gaps (2006 - 2007).

*Evaluation of Perchlorate Plume, Rancho Cordova, CA*

Ms. Stanin provided hydrogeologic and litigation support for an industrial facility near Rancho Cordova. This area is characterized by commingled perchlorate plumes with impacts to offsite water supply wells. Technical evaluations directed by Ms. Stanin included groundwater contaminant characterization, plume delineation, source identification, and water supply impacts.

*Evaluation of Perchlorate Impacts to Municipal Wells, Santa Clarita Valley, CA*

Ms. Stanin provided hydrogeologic and litigation support for four water agencies with water supply wells impacted by perchlorate near Santa Clarita in Southern California. Her work involved an evaluation of the fate and transport of contaminants including perchlorate from a nearby industrial facility including impacts to surface water and groundwater. The study also evaluated use of pumping water supply wells for plume containment and other remedial strategies. Ms. Stanin has also served as a technical representative of the water companies to state and local agencies. This work included a technical presentation of perchlorate in water supply wells to Assemblyman Keith Richman and technical presentations to DTSC and working with DTSC to develop remedial options.

*Fate and Transport of NDMA for WateReuse Foundation*

Ms. Stanin served as Lead Hydrogeologic Investigator for a research project on the fate and transport of NDMA in the saturated zone. The project was funded by the WateReuse Foundation and participating water agencies and was conducted in concert with researchers from the University of California Berkeley, University of California Riverside, Arizona State University, and Todd Engineers (now Todd Groundwater). NDMA occurrence in groundwater was analyzed at four sites in California to analyze evidence of degradation or attenuation of NDMA in the saturated zone. NDMA releases were from historical industrial sources, artificial recharge of chlorinated wastewater into spreading basins, and the injection of treated wastewater into hydraulic barriers for seawater intrusion. Results were published in WateReuse publication *Investigation of N-Nitrosodimethylamine (NDMA) Fate and Transport*, 2006 (ISBN: 0-9747586-6-3).

*Environmental Investigations, San Gabriel Valley Superfund Site, Los Angeles County, CA*

Ms. Stanin served as project manager for environmental investigations and remedial measures for a landfill site in the San Gabriel Basin. This included a regional groundwater investigation over a 50 square-mile area of the basin, analysis of conjunctive use at the Santa Fe Spreading Grounds, and evaluation of the impacts on local groundwater flow directions and contaminant transport. The project also involved hydrogeologic support for construction and calibration of a three-dimensional finite difference flow model. Work also included specific hydrogeologic evaluations, groundwater modeling, identification and evaluation of Potential Responsible Parties (PRPs), allocation alternatives, impacts to water supply wells, and support on numerous regulatory, technical, and Superfund issues. Todd subsequently provided compliance with the site's Monitoring and Mitigation Program.

**Underground Injection Control (UIC) Program Experience**

*Class I UIC Permit, California Specialty Cheeses, San Joaquin County, CA*
Ms. Stanin prepared a successful Class I UIC permit application package for California Specialty Cheeses for deep injection of cheese processing wastes near Lathrop, CA. The application included an independent geologic assessment of subsurface stratigraphy and lithology, structural setting, target zones for injection, preparation of response plan, and estimated injection capacity. The application was approved by the U.S. Environmental Protection Agency, Region IX, with only minor modification. The Class I permit was only the third such permit that had been issued in California at that time. Follow on work included planning for the drilling and installation for injection wells (2005 – 2007).

*Deep Injection Feasibility Study, City of Goodyear, Maricopa County, AZ*
Ms. Stanin was project manager for a feasibility study for deep injection of brine generated from the City's groundwater treatment program. The study involved an assessment of the regional geology and hydrogeology, including research on potential injection near a subsurface salt deposit. The project also involved assessment of the U.S. Environmental Protection Agency's (USEPA) UIC regulations for Arizona. Preliminary costs and recommendations for additional investigation were provided. Limitations and data gaps were identified to assist the City with additional evaluation, if warranted (2006).

**Groundwater Expert Witness and Peer Review Experience**

*Expert on a Confidential Well Failure, Kern County, CA*
Ms. Stanin provided expert witness and deposition testimony for a consulting firm being sued for failure of a deep irrigation well. The case involved a review of regional groundwater conditions, construction, production, and specific capacity data for nearby irrigation wells, and daily records of drilling, development, and testing. The case also involved Standard of Care practices for well drilling. The case settled favorably for the defendant. (2013 – 2014).

*Court-appointed Expert on Groundwater Impacts near Stockton, CA*
Ms. Stanin provided expert hydrogeologic support to the Eastern District in US District Court during a settlement conference between plaintiffs and defendants. The support involved a written assessment of the source of soil and groundwater contamination at a former industrial site including transport and timing of release. Support for the settlement conference included development of a timeline for remedial activities and regulatory compliance (2012).

*Expert on Groundwater Fate and Transport, Orange County Water District, Orange County, CA*
Ms. Stanin provided expert witness and litigation support services to Orange County Water

District regarding impacts to water supply wells from perchlorate and volatile organic compounds (VOCs). The case, Orange County Water District, plaintiff, vs. Sabic Innovative Plastics US, LLC, et al., defendants, was filed in California Superior Court, County of Orange in 2008. Ms. Stanin provided six days of deposition testimony from April through November 2009 regarding the analysis of potential sources of contaminants.

*Expert on Groundwater Fate and Transport, Santa Clarita, CA*
Ms. Stanin provided expert witness and litigation support services to four water companies with water supply wells impacted by perchlorate near Santa Clarita, California. The case, Castaic Lake Water Agency, Newhall County Water District, Santa Clarita Water Company, and Valencia Water Company, plaintiffs, vs. Whittaker Corporation; Santa Clarita, LLC; Remediation Financial, Inc.; and Does 1-10, Inclusive, defendants, was filed in United States District Court, Central District of California. Project work involved an evaluation of the fate and transport of contaminants including perchlorate from a nearby industrial facility including impacts to surface water and groundwater. Ms. Stanin assisted with preparation of an expert report, several Declarations, and provided deposition testimony (2003 – 2007).

*Groundwater Expert/Peer Review Panel for Redwood City, CA*
Ms. Stanin was asked to evaluate the feasibility of drilling water supply wells associated with a proposed development on San Francisco Bay, referred to as the Saltworks project. The evaluation process examined the feasibility of the proposed sources of supply to determine if the City should proceed with the development of an Environmental Impact Report (EIR) in compliance with CEQA. Ms. Stanin also conducted an assessment of potential groundwater use and well locations to provide back-up water supply to the City (2009 – 2011).

*Expert on Landfill Litigation Loss of Permit, Harris County, TX*
Ms. Stanin provided expert witness and litigation support for a lawsuit against an insurance company for groundwater contamination and loss of an operating permit (Browning Ferris Industries vs. Certain Underwriters of Lloyds of London, et al.). Project work involved the examination of California Chapter 15 permitting requirements over time and groundwater contaminant fate and transport evaluations. Ms. Stanin provided an expert report, numerous affidavits, and deposition testimony (2004-2008).

*Litigation Support, Municipal Landfill, Fresno County, CA*
Ms. Stanin served as an Expert Witness on groundwater contamination in a civil litigation against a hazardous waste hauler for asbestos disposal in a landfill in Fresno, California. Technical components of the project include characterization of local groundwater contamination, regional groundwater flow, and vadose zone contaminant transport (1997).

*Peer Review of Contamination Characterization, Los Angeles County, CA*
Ms. Stanin provided a peer review and hydrogeologic analysis for a metals recycling facility in Los Angeles County. Analysis included groundwater elevation and contaminant plume mapping, identification of chemicals of concern including VOCs and petroleum hydrocarbons, evaluation of soil gas data, meeting with regulatory agencies, and preparation of a site-wide technical report.

**Publications / Panels / Presentations**

*Approach to Groundwater Impacts Analysis, DOGGR SB 4 EIR*, Invited Speaker, Groundwater Resources Association Symposium, Oil Gas and Groundwater in California, Wise Production and Protection of our Valuable Natural Resources, February 18, 2015.

*Groundwater Replenishment in the Seaside Basin: Increasing Basin Yield with Recycled Water*, 14th Biennial Symposium on Managed Aquifer Recharge, Groundwater Resources Association and Arizona Hydrological Society, July 31, 2014.

*Recharge in the Ames Valley: Making it Happen*, with D. Craig and E. Lin, Todd Engineers and M. West, Bighorn-Desert View Water Agency, Managed Aquifer Recharge Symposium, Increasing Opportunities for Groundwater Storage, National Water Resources Institute (NWRI), January 26, 2011.

*Deep Well Injection for Brine Disposal*, invited Speaker on Challenges and Progress in Developing Brackish Groundwater as a Sustainable Water Supply Panel, 9th Annual Multi-State Salinity Coalition Summit, January 2009.

*Benefits of Recycled Water Recharge of a Coastal Groundwater Basin*, with T.G. Cole, R.B. Chalmers, and R.B. Holden, proceedings of the WateReuse Association Annual Conference, Seattle, WA, September 2009.

*Complexities of Using Recycled Water to Recharge an Over-drafted Groundwater Basin*, with T.G. Cole, R.B. Chalmers, and R.B. Holden, proceedings of the WateReuse Association Annual Conference, Newport Beach, CA, March 2008.

*Storing Water in California Desert Basins: Selection of Managed Aquifer Recharge Sites in the Ames Valley Groundwater Basin San Bernardino County, CA*, with E. Lin, A. Garcia, and L. Eckhart, at “Increasing Groundwater Storage to Meet California’s Future Demand: Challenges and Solutions”, Groundwater Resources Association, 3rd Symposium in the Groundwater Resource Series, June 2007.

*Investigation of N-Nitrosodimethylamine (NDMA) Fate and Transport*, WateReuse Foundation publication 02-002-01, IBSN: 0-9747586-6-3, Copyright 2006 (Research Project Team Member with Todd Engineers, University of California Berkeley, University of California Riverside, and Arizona State University funded by WateReuse Foundation).

*Challenges for Recharge of Recycled Water, at “Assessment, Use, and Management of Groundwater in Areas of Limited Supply*,” Groundwater Resources Association (GRA) 15th Annual GRA Meeting and Conference, San Diego, California, September 21, 2006.

*The Occurrence, Fate, and Transport of NDMA in California Groundwater, Five Case Studies*, at "Emerging Contaminants in Groundwater: A Continually Moving Target," Groundwater Resources Association (GRA) 18th Symposium on Groundwater Contaminants, Concord, California, June 7-8, 2006.

*Stable and Other Isotope Techniques for Perchlorate Source Identification*, with W. Motzer, T. Mohr, S. McCraven, Environmental Forensics, v. 7, no. 4, pp 89-100, March 2006.

*Perchlorate: 20th Century Contaminant – 21st Century Solutions*, with W. Motzer, Southwest Hydrology, v.2, n. 6 (November/December 2003 issue), pp.24-26.

*Hayfield Conjunctive Use*, at "Sustaining Groundwater Resources, the Critical Vision," Groundwater Resources Association (GRA) 11th Annual GRA Meeting and Conference, Newport Beach, California, September 18-19, 2002.

East Meets West – National Water Solutions, invited Speaker on Water Quantity Issues Panel, Water Resources Conference, Holland & Knight, University of Florida, October 2001.

*Optimizing Groundwater Management Strategies in the Edwards Aquifer*, with D.K. Todd, in Proceedings of the World Water and Environmental Resources Congress, May 20-24, 2001, Orlando, Florida, Don Phelps and Gerald Sehlke, editors.

*Challenges to Conjunctive Use Programs*, with D.K. Todd and I. Priestaf, invited Conference Talk Conjunctive Use: Successful Experiences and New Frontiers, educational conference sponsored by Association of Ground Water Agencies and the American Ground Water Trust, April 11-12, 2001, Ontario, California.

**Professional Contributions**

Managed Aquifer Recharge (MAR) Standards Committee, American Society of Civil Engineers (ASCE) and Environmental Water Resources Institute (EWRI), MAR Guidelines Development Subcommittee, 2004 to present.

American Water Works Association (AWWA), Member of the Water Resources Management Delegation to Cuba, 2002.

## Hydrology and Water Quality: Surface Water

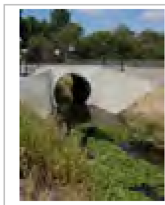
**Schaaf and Wheeler Consulting Civil Engineers**
**(Daniel Schaaf, P.E. and Andrew Sterbenz, P.E.)**

***This page is intentionally blank.***

# Schaaf & Wheeler

Schaaf & Wheeler is a 32-person civil engineering firm, with 17 California registered professional engineers. Our experienced engineers comprehensively resolve water resources issues throughout California and the western United States. Our projects generally range from large flood control projects and FEMA flood insurance studies to local agency public works infrastructure projects – water, recycled water, sewer, and storm drain planning and design. Although certified by the State of California as a small business enterprise (certification #40527), Schaaf & Wheeler has a broad reach. Our engineers operate from four locations: Salinas, Santa Clara, San Francisco, and Santa Rosa.

*Schaaf & Wheeler ranks among the top 25 engineering firms in Silicon Valley, as compiled by the San José Business Journal (December 2014) and is the only firm listed to focus exclusively on water projects.*



## Areas of Focus

Schaaf & Wheeler has ten areas of focus within the water resources discipline.

- Hydrology and hydraulics analyses, including site evaluations and modeling;
- Flood control analyses, including floodplain studies and channel design, filing of letters of map revision, and FEMA coordination;
- Watershed assessments, erosion and sediment control, and bioengineered channel stabilization;
- Stormwater management and drainage services, including master planning, engineering, and design of urban storm drain systems and pump stations;
- Water quality, including design or review of best management practices (BMPs) for storm water treatment and hydromodification flow control facilities;
- Potable water system master planning, modeling, engineering; and design of supply, storage, collection and distribution systems, including tanks and booster stations;
- Waste water system master planning, engineering, and design of conveyance systems, including lift stations;
- Recycled water systems planning, engineering, and design; including reclamation feasibility studies and customer retrofits;
- Construction management, construction site observation, construction inspection services, value engineering, construction cost analysis, and constructability reviews;
- Project management, including management of subconsultants, containment of schedule and cost, and communications with client and stakeholders.

## Experience in Monterey County

Schaaf & Wheeler has prepared numerous reports and studies in Monterey County:

- Reclamation Ditch: Development of the HEC-RAS model of the Reclamation Ditch for the Monterey County Water Resources Agency. Prepared the Zone 9 Impact Fee Study and Nexus Report for development stormwater impact fees.
- Salinas River Lagoon Fish Screen, 2009-2011, Old Salinas River
- Potrero Road Tide Gate Configuration and Performance Study, 2000, Old Salinas River
- Carr Lake Multi-Purpose Flood Control Study, 2002, portion of the Reclamation Ditch system
- Bryant Canyon Flood Control Improvements (Soledad), 2005-2007, tributary to the Salinas River
- Castroville Pump Station, 2005, tributary to Moro Cojo Slough.
- Blanco Drain Pump Station, 2007, tributary to Salinas River
- Espinosa Pump Station, 2007-2008, tributary to the Reclamation Ditch
- Santa Rita Pump Station, 2003-2004, tributary to Reclamation Ditch.
- Jarvis Lateral Erosion Protection, 2007-2008, tributary to Santa Rita Creek.
- Upper Merritt Lake Hydraulic Analysis, 2012, floodplain study.
- City of Seaside, Dry Weather Stormwater Diversion Pump Station Design, 2008-2010.
- CSU-Monterey Bay, Storm Water Master Plan, 2005.
- Fort Ord Stormwater System Assessments, 2000, prepared for the Fort Ord Reuse Authority.

## Daniel J. Schaaf, PE – Vice President - Schaaf & Wheeler

**Education**

BSCE, San Jose State University

MSCE (Water Resources Engineering), San Jose State University

**Licenses**

Registered Civil Engineer, California #C57617

**Affiliations**

American Society of Civil Engineers

Floodplain Management Association

**Daniel J. Schaaf, PE** has 20 years of project experience encompassing the areas of flood control and drainage, surface water hydrology, and physical and numerical modeling. Dan has managed several large hydrology/hydraulics, flood control and drainage projects. He is skilled in open channel hydraulics, coastal and estuary processes, 1D and 2D modeling, floodplain mapping and storm drain master planning. He is currently working on implementing modeling projects that integrate pipe and surface flows using sophisticated 2D modeling software. He has performed several FEMA Flood Insurance Studies and Letters of Map Revisions for clients throughout California. He is proficient in modeling and GIS software: GeoHEC-HMS, GeoHEC-RAS, TRIM3D, RMA-2, RMA-10, MIKE 11, MIKE 21, MIKE-URBAN, MOUSE, EPA SWMM, Cybernet, InfoSWMM, InfoWorks, QUAL2E, EPA-Net, ArcGIS 10.0, Spatial Analyst, 3D Analyst, AutoCAD Map and ArcIMS.

### Major Project Accomplishments

#### Planning and Design

Storm Drain Master Plan – City of East Palo Alto (2014)
North Bayshore Storm Drain Master Plan – City of Mountain View (2014)
North San Jose Drainage Master Plan - City of San Jose (2013)
Stormwater Master Plan - City of Los Altos (2011)
Stormwater Master Plan - County of Santa Cruz (2009-2010)
El Charro Specific Plan Channel Design – City of Livermore (2005-2010)
Northside Pump Station Design - City of Alameda, Public Works Department (2010)
Storm Drain Master Plan and Sea Level Rise Study – City of Alameda (2008-2010)
Storm Drain Master Plan - City of Paso Robles (2007)
Program Management for Storm Drain CIP– City of Belmont Public Works (2005)
Storm Drain Master Plan - City of San Mateo (2004)
Storm Drain Master Plan and Subsequent Update – City of Livermore (2003)

#### Hydrology and Hydraulics

Hydrologic & Hydraulic Model for Zone 7 Watershed – Zone 7 Water Agency (2014)
Greenwood Road Culvert Replacement Hydrologic Study – County of Napa (2014)
Oakville Cross Road Bridge Replacement No-Rise Study - County of Napa (2014)
Groundwater Replenishment Project EIR Hydrology - Urban Runoff Capture at Lake El Estero – City of Monterey (2013 -2014)
Review of Hydraulic Model for Lower Carmel River – Carmel Area Wastewater District (2013 – 2014)
City of Sebastopol Northeast Area Specific Plan EIR – Placeworks (2005 – 2008)
Isabel Interchange, Livermore, Storm Drain Alignments – Mark Thomas & Associates (2006)
Pajaro River Breaching Alternatives - County of Santa Cruz (2006-2007)
El Charro Specific Plan Hydrology Study - City of Livermore (2005-2009)
Napa Sonoma Salt Marsh Restoration - US Army Corps of Engineers (1999)
Highway 46/101 Drainage Study - City of Paso Robles (2008-2009)

#### Floodplain Management

Livermore Airport Flood Protection Planning – City of Livermore (2015)
Dam Break Analyses and Inundation Mapping for Little Grass Valley, Sly Creek, and Lost Creek Dams – South Feather Water Agency (2015)
Bear Gulch Station 46 Tank Failure Inundation Study – California Water Resource Company (2015)
Silicon Valley BART Extension Floodplain Study - Valley Transit Athority (2012)
San Tomas Aquino Flood Study - Santa Clara Valley Water District (2012)

Last Updated: August 25, 2015

Salt Creek Floodplain Analysis - Private Owner Redding (2012)
Flood Analysis and Bayfront Levee Wave Analysis - City of San Mateo (2010)
Arroyo Las Positas and Arroyo Mocho CLOMR - City of Livermore (2011)
Southern California Wildfire Post Fire Flood Study - FEMA (2003 and 2007)
Phelps Creek LOMR - UC Sanata Barbara (2009); Soscol Gateway Drainage Study - City of Napa (2005)
Hooke Creek Flood Insurance Study - San Bernardino County, FEMA (2005)
Mint Canyon Flood Insurance Study - Los Angeles County, FEMA (2008)

**River and Stream Enhancement**

Altamont Creek Oil Removal Study - City of Livermore (2009-2010)
East Arm Mountain Lake Enhancement, San Francisco - The Presidio Trust (2005)
Reclamation Ditch Channel Study - Monterey County Water Resources Agency (Ongoing)
South Bay Pond Interim Management Plan - Cargill Salt (2000-2004)

## Andrew A. Sterbenz, P.E. – Senior Engineer – Schaaf & Wheeler

**Andrew A. Sterbenz, P.E.** has over 25 years of experience managing engineering organizations and solving engineering problems, and is recognized for developing and implementing creative solutions to complex problems. In 2006-2007 and 2012-2013 he served as the full-time District Engineer for the Marina Coast Water District, managing a $150 million water and sewer capital improvements budget that includes the development of new groundwater, recycled and desalinated water supplies for the former Fort Ord. He has prepared long-range water supply plans in California and Texas. Plans include the projection of population and water demands, the assessment of current water supply availability, and the analysis of water management strategies to meet projected shortages. He is adept at analyzing, researching, planning, coordinating and executing strategies to achieve organizational goals. Andy has prepared detailed plans and specifications for bidding and construction for public agencies, and managed construction projects for the client agencies. He has conducted environmental studies and remediation design, and assisted with environmental permitting. He is well experienced with state and federal environmental regulations.

### Major Project Accomplishments

#### Water and Wastewater Systems Planning and Design

Pure Water Monterey Groundwater Replenishment Project – Denise Duffy & Assoc. – Monterey County, CA (2013-2015)
Reclamation Ditch Yield Study – Monterey Penninsula Water Management District - Monterey County, CA (2013-2014)
Blanco Drain Yield Study – Monterey Penninsula Water Management District - Monterey County, CA (2013-2014)
Aptos Booster Pump Station – Soquel Creek Water District – Aptos, CA (2012-2015)
McGregor Drive Booster Pump Station – Soquel Creek Water District – Capitola, CA (2012-2015)Interim District Engineer - Marina Coast Water District - Marina, CA (2006-2007, 2012-2013)
Soquel Drive Cast Iron Main Replacement-Soquel Creek Water District-Soquel, CA (2012)
Watkins Gate Well and Pipeline– Marina Coast Water District – Marina, CA (2011-2012)
Stonegate Water Supply Project – San Benito County Public Works-Hollister, CA (2011-2013)
Castroville Community Plan Infrastructure Estimate – Monterey County Redevelopment Agency – Monterey, CA (2009-2010)
Sewer Feasibility Study for Commercial Parkway – Monterey County Redevelopment Agency – Castroville, CA (2010)
Boronda Meadows General Development Plan Peer Review – PMC, Inc. – Salinas, CA (2010)
Modular Wastewater Treatment System - LOGCAP – Balkans, Yugoslavia (1999)

#### Water Delivery Systems

Raw Water Pump Station Design and Construction - Coastal Water Authority - Houston, Texas (2000)
Moses Bayou 84-Inch Siphon - Gulf Coast Water Authority - Texas City, Texas (2001)
System Water Audit - Gulf Coast Water Authority - Texas City, Texas (1999)

#### Water Supply Planning

2010 Urban Water Management Plan – Marina Coast Water District – Marina, CA (2010-2011)
Regional Urban Water Augmentation Project - Marina Coast Water District - Marina, CA (2006-2007)
Region H Water Plans (2001 and 2006) - San Jacinto River Authority - Conroe, Texas (1998-2001, 2002-2006)

Colorado River Water Availability Model - Texas Natural Resource Consv. Comm. – Austin, TX (2002)

**Stormwater Planning and Design**

Bryant Canyon Channel – Monterey County Water Resources Agency – Soledad, CA (2013 –2014)
Wrigley-Ford Creeks Maintenance Project – City of Milpitas – Milpitas, CA (2011-2012)
Reclamation Ditch Repair at Alisal St – Monterey County Water Resources Agency – Salinas, CA (2009)
Pajaro River Levee Maintenance Design – Monterey County Water Resources Agency – Salinas, CA (2009)

# Noise and Vibration

Michael S. Thill, Illingworth & Rodkin

**MICHAEL S. THILL**

Mr. Thill is a principal of the firm with 17 years of professional experience in the field of acoustics. His expertise includes performing field research, analyzing data, and noise modeling. He has conducted numerous field surveys in a variety of acoustical environments to quantify airborne noise levels, groundborne vibration levels, and hydro-acoustic noise levels. He has analyzed and summarized complex sets of data for inclusion into noise models. Mr. Thill has been trained, and is a regular user of FHWA's Traffic Noise Model (TNM), and is familiar with federal and State procedures for preparing highway noise study reports.

Mr. Thill has authored technical noise reports for various land use proposals including residential, commercial, educational, and industrial developments. He has managed the General Plan Update noise studies for several communities in California and has recommended policy language in order to maintain compatible noise levels community-wide. Some of his recent major projects have included the assessment of noise and vibration from quarry expansion projects, groundwater recharge projects, and winery projects where operations and special events have been of concern in rural settings. He has vast experience explaining acoustical concepts and the results of his analyses in public forums to the general public and project decision-makers.

Mr. Thill has also led traffic noise investigations for major transportation projects including the Route 4 Bypass project (2003 to 2013) and the I-680/Route 4 Interchange project (2014 to 2015) in Contra Costa County, California. He managed the noise study reports the US Highway 101 and State Route 85 Express Lanes projects for the Santa Clara County Valley Transit Authority (2011 to 2013), proposed along 66 miles, combined, of project study area between Mountain View and Morgan Hill, California. In 2015, Mr. Thill is leading the analyses of noise impacts and noise abatement for the US Highway 101 / State Route 84 Interchange Project in Redwood City, California and the US Highway 101 / Hearn Avenue Interchange Project in Santa Rosa, California.

## SUMMARY

Ms. Nellor has over 38 years of professional experience in the environmental field including water and wastewater quality management; water recycling (potable reuse and non-potable reuse); regulatory permitting and compliance; regulatory and legislative policy development and analysis; research; and source control and pollution prevention. She is also very active in professional activities related to the environmental profession.

## PROFESSIONAL EXPERIENCE

2005 – Present: *Nellor Environmental Associates, Inc.*
President, Nellor Environmental Associates, Inc. (NEA), an environmental engineering consulting firm that provides technical services and assistance related to water reclamation and wastewater management. NEA has been certified as a Disadvantaged Business Enterprise in Texas and California, and as a Women's Business Enterprise by the City of Austin, Texas. Specific areas of experience include:

- Permitting/Regulatory Assistance - Ms. Nellor has provided technical review and analysis, developed formal regulatory comments, and prepared hearing testimony for numerous wastewater discharge and water reuse permits, including the seven permitted potable reuse projects in California (Montebello Forebay Groundwater Recharge Project, Chino Basin Groundwater Recharge Project, Groundwater Replenishment System, West Coast Basin Barrier Project, Alamitos Barrier Project, Dominguez Gap Barrier Project, and the Cambria Emergency Water Supply Project). Examples include:
  - Engineering Report and water recycling permit for the expansion of the Alamitos Barrier Project
  - NPDES Permits for the City of Los Angeles, CA: D.C. Tillman Water Reclamation Plant, Los Angeles/Glendale Water Reclamation Plant, Terminal Island Water Reclamation Plant and Hyperion Treatment Plant
  - NPDES Permits for the County Sanitation Districts of Los Angeles County's Joint Water Pollution Control Plant and Whittier Narrows Water Reclamation Plant
  - NPDES Permit for the West Basin Municipal Water District's Demonstration Desalination Project
  - NPDES Permit for the Las Virgenes Municipal Water District
  - NPDES Permit, General Permit, and Los Angeles County Storm Water Permit for the Castaic Lake Water Agency
  - NPDES Permit for the Newhall Ranch Water Reclamation Plant
  - Waste Discharge and Water Recycling Requirements for the City of Los Angeles, CA Donald C. Tillman and Los Angeles Glendale Water Reclamation Plants
  - Waste Discharge and Water Recycling Requirements and technical assistance for the West Basin Municipal Water District's West Basin Coast Basin Barrier Recycled Water Project Expansion
  - Waste Discharge and Water Recycling Requirements for the for the County Sanitation Districts of Los Angeles County's Lancaster Water Reclamation Plant
  - Permitting Issues Related to Groundwater Recharge for the for the County Sanitation Districts of Los Angeles County's Palmdale Water Reclamation Plant
  - Mandatory Minimum Penalties for the County Sanitation Districts of Los Angeles County's Valencia Water Reclamation Plant
  - Technical Assitance for Enforcement Actions or Litigation Related to NPDES Permits and Industrial Waste Permits
  - Regulatory Assistance for City of Phoenix 23rd Ave. and 91st Ave. Treatment Plants
  - Regulatory Assistance for the City of Vacaville, CA
  - Regulatory Options for Wet Weather Discharges for the Lake Arrowhead Community Services

District

- Policies/Regulations - Ms. Nellor has worked on numerous policies, regulations, and special studies including water recycling criteria, water quality standards, salt nutrient management plans, antidegradation regulations, whole effluent toxicity testing, impairment determinations, and total maximum daily loads. She serves as an advisor to the California Division of Drinking Water for the development of Groundwater Recharge and Reuse Regulations, has served as a technical advisor to WateReuse California for the development of the Water Recycling Policy and the Scientific Advisory Panel for Constituents of Emerging Concern (CECs), and was a co-author of *Direct Potable Reuse: the Path Forward* sponsored by the WateReuse Association, the WateReuse Research Foundation, and the National Water Research Institute. She is also providing technical advise to the Texas Commission on Environmental Quality regarding potable reuse. Other examles include:
  - U.S. EPA's Recreational Water Quality Criteria
  - U.S. EPA's Draft Guidance for Implementing Methylmercury Water Quality Criterion
  - California State Water Resources Control Board Recycled Water Policy and CEC Monitoring
  - California State Water Resources Control Board General Irrigation Permit
  - California State Water Resources Control Board Policy for Implementation of Toxics Standards for Inland Surface Waters, Enclosed Bays, and Estuaries of California (SIP and Amendments)
  - California State Water Resources Control Board Chlorine Residual Policy
  - California State Water Resources Control Board's Effluent Dependent Water Bodies and Mercury Workgroup
  - California State Water Resources Control Board Ocean Plan Amendments and Triennial Reviews (including the Brine Discharge Policy)
  - California State Water Resources Control Board Proposed Methylmercury Water Quality Objectives for Inland Surface Waters and Enclosed Bays and Estuaries
  - California State Water Resources Control Board Proposed San Francisco Bay-Delta Mercury Offset Policy
  - Los Angeles Regional Water Quality Control Board Basin Plan and Triennial Reviews

- Planning and Compliance Strategies – Ms. Nellor has worked on numerous projects to identify, evaluate, develop, and recommend the most cost effective options for water recycling and wastewater management. She specializes in analyzing the impacts of regulations on compliance and implementation strategies, including master planning studies for potable reuse projects, salt/nutrient management, source control, CEQA/NEPA reviews, and antidegradation. Projects include:
  - PURE Water Monterey Groundwater Replenishment Project Environmental Impact Report
  - Texas Water Development Board Evaluating the Potential for Direct Potable Reuse in California
  - Texas Water Development Board State of Technology of Water Reuse, 2011 Water Reuse Research Agenda, and History of Water Reuse in Texas
  - Texas Water Development Board Direct Potable Reuse Resource Document
  - City of Lancaster, CA Groundwater Recharge Feasibility Study and Fatal Flaw Analysis
  - City of Oceanside, CA Indirect Potable Reuse and Pathogen Removal Study
  - Metropolitan Water District of Southern California's Joint Groundwater Replenishment Feasibility Study
  - Alternatives Assessment and Preliminary Design for the Water Replenishment District of Southern California's Groundwater Reliability Improvement Program
  - As-Needed Engineering Technical Services Consultant for Pure Water San Diego Program
  - California Environmental Quality Act public health and regulatory assistance for the Central and West Coast Basin Groundwater Master Plan and the Monterey Peninsula Groundwater Replenishment Project
  - City of Los Angeles Groundwater Recharge Master Planning Process
  - City of San Diego Surface Water Augmentation Demonstration Project
  - Eastern Municipal Water District Indirect Potable Reuse Phase I Facilities Planning Study
  - East Valley Water District Indirect Potable Reuse Feasibility Study and Implementation Program
  - Rancho California Water District Indirect Potable Reuse Conceptual Design Study
  - South Sacramento County Agriculture & Habitat Lands Recycled Water Project Programmatic

Feasibility Study
- Upper San Gabriel Valley Water District Indirect Potable Reuse Feasibility Study
- Santa Clara Valley Water District Potable Reuse Project Plan
- Recycled Water Recharge Feasibility Study
- Montebello Forebay Groundwater Recharge Project Expansion
- Central and West Basin Salt Nutrient Management Plan
- White Paper for the National Water Research Institute on the *Status of the Water Recycling 2030: Recommendations of California's Recycled Water Task Force*
- White Paper for WateReuse California on *Public and Political Acceptance of Direct Potable Reuse*
- California State Implementation Policy Database Development
- Government Accounting Office Study on the Cost of Federal Water Requirements
- San Jose / Santa Clara Salinity Study
- Southern California Water Recycling Projects Initiative Water Quality Technical Memorandum No. 5 *Potential Salinity Impacts to Recycled Water*
- Water Recycling Site Inspection Program, Regulations and User Handbook for the County Sanitation Districts of Los Angeles County
- Water Sofener Rebate Program for County Sanitation Districts of Los Angeles County
- Upper Santa Clara River Chloride Total Maximum Daily Load
- City of Austin TX Water Utility - Assessment of Requirements for Auxiliary Water
- Copper Analytical Issues for the City of Santa Rosa, CA
- Monograph on Adaptive Implementation of TMDLs

- Source Control – Ms. Nellor has worked on numerous projects to related to evaluating and recommending source control strategies; Projects include:
    - Review and evaluation of the City of Los Angeles source control program related to compliance with California Department of Public Heath draft groundwater recharge regulations.
    - Review and evaluation of the Orange County Water District's source control program and Santa Ana Watershed Project authority's source control programs related to increased use of recycled water for the Groundwater Replenishment Project.
    - Development of national strategy for the National Association of Clean Water Agencies regarding development of local limits for conventional and nonconventional pollutants.

- Research - Ms. Nellor is involved with a number of research projects related to the use of recycled water and management of wastewater, and serves on numerous project advisory committees. She was the Principal Investigator for WateReuse Research Foundation projects WRF-06-018 *Tools to Assess and Understand the Relative Risks of Indirect Potable Reuse Projects* and WRF-08-01 *Developing Standards/Criteria for Various End Uses of Recycled Water*. She was on the research team for WRF projects 09-02 *Framework for Informed Planning Decisions Regarding Potable Reuse and Dual Pipe Systems* and 10-14 *The Future of Purple Pipes: Exploring the Best Use of Non-Potable Recycled Water in Diversified Urban Water Systems*. She also participated as a contributor to the WateReuse Research Foundation's *Best Practices for Developing Indirect Potable Reuse Projects*. She has served on research advisory committees for the WateReuse Research Foundation and the Water Environment Research Foundation.

1995 – 2005: *County Sanitation Districts of Los Angeles County*
The Sanitation Districts provide for the wastewater and solid waste management needs of over 5 million people in 78 cities and portions of Los Angeles County, California. Ms. Nellor was the Assistant Department Head of Technical Services. This position is responsible for the overall administration of the agency's water reclamation and research programs and water quality permit and compliance programs for the agency's wastewater, biosolids, and solid waste management facilities. She was responsible for managing all water recycling and wastewater permitting activities, including permit amendments, revisions, petitions, and litigation. She was responsible for liaison activities with federal, state and local governmental agencies on legislative and regulatory issues, including the Los Angeles Basin Plan, the California Toxics Rule, the State Implementation Plan, the California Ocean Plan, and the State Mandatory Minimum Penalty Program. Ms. Nellor was also the co-project manager for a Water Research Foundation $10 million

water recycling research project related to the efficacy and sustainability of using recycled water for groundwater replenishment.

1991 – 1995: *Orange County Sanitation District*
The District provides for the wastewater management needs of over 2 million people in Orange County, California. Ms. Nellor was the Acting Head of the Technical Services Department, which was responsible for the agency's air and wastewater quality, permitting and compliance programs, research programs, source control and pollution prevention programs, and recycling activities (water and biosolids). She was also responsible for liaison activities with federal, state and local governmental agencies on legislative and regulatory issues. During her tenure at the District, she also served as the head of the agency's source control program.

1977 – 1991: *County Sanitation Districts of Los Angeles County*
Ms. Nellor was responsible for managing the agency's source control and industrial pretreatment program. During her tenure at the Sanitation Districts, she held other positions responsible for water recycling permitting and implementation; wastewater management, permitting and compliance activities; and water recycling research. Ms. Nellor was the project manager of a $3 million water recycling research project related to the health effects of using recycled water for groundwater replenishment.

**EDUCATION:**
M.S. Environmental Health Engineering
B.S. Civil Engineering, University of Texas at Austin

**REGISTRATION**: Registered Civil Engineer
California (No. 31997)
Texas (No. 95405)

**CERTIFICATION**:
Texas: Disadvantaged Business Enterprise and City of Austin Women's Business Enterprise
California: Disadvantaged Business Enterprise

**AWARDS**
Association of Metropolitan Sewerage Agencies President's Award
Order of the Silver Cover, California Water Pollution Control Association
University of Texas Civil and Architectural Engineering Academy of Distinguished Alumni
WateReuse Association, CA Section, Recycled Water Advocate of the Year, 2005
National Association of Clean Water Agencies, 2006 Distinguished Performance Award
National Association of Clean Water Agencies Hall of Fame

**SOCIETIES**
American Society of Civil Engineers
Association of Clean Water Agencies
- Served on Board of Directors
- Served as Chair Regulatory Policy Committee
- Served as Co-Chair Mercury Workgroup, current member
- Member Emerging Contaminants Workgroup
- Member Pathogen Workgroup

Environmental Protection Agency's Effluent Guidelines Task Force
- Served as Co-Chair
- Served as member

Tri-TAC
- Past Chair (1996-99)
- Member

Water Environment Association of Texas
Water Environmental Federation
- Water Reuse Committee

Long Range Planning Committee (2005-2006)
Chair Pollution Prevention Committee (1993-1995)
Chair, Ad Hoc Source Control Committee (1991-1993)

Water Environment Research Foundation
Research Council (2001-2007)
Trace Organics Issue Area Team

WateReuse Association
Board of Directors (1997 – 2008)
Past President (2001 -2003)
Regulatory Committee
Potable Reuse Committee

WateReuse Foundation
Past Vice President Board of Directors (2000 – 2005)
Research Advisory Committee (2005-2010)

University of Texas Engineering Foundation Advisory Council of the College of Engineering (2005 – 2008)

## Education

•Ph.D. Civil & Environmental Engineering, *University of California, Berkeley*
•M.S., Civil & Environmental Engineering, *University of California, Berkeley*
•B.S., Civil Engineering, *Virginia Tech, Blacksburg*

## Registration

Civil Engineer, State of California – No. 78671

## Summary

Dr. Gordon Williams is a Supervising Engineer at Trussell Technologies, and a B.S. from Virginia Tech and a M.S. and Ph.D. from the University of California at Berkeley. Dr. Williams has 10 years wastewater and water reuse experience. In his doctoral work, Dr. Williams studied granular-media rapid-depth filtration for water reuse and focused on understanding how loading rate impacts tertiary filter performance. As a result of his research, several California wastewater treatment facilities are able to maximize their recycled water production by operating at loading rates up to 7.5 gpm/ft$^2$, which is 50% higher than the 5 gpm/ft$^2$ limit specified by the California Title-22 Water Recycling Criteria. Williams also has expertise in understanding pathogen reduction through tertiary treatment and has identified particle association as an important factor in the removal of viruses through tertiary granular-media filtration. His recent projects have included: increasing the filtration rate for the Daly City water reclamation plant, determining the media configuration for the City of Santa Cruz's filter rehabilitation, and designing a new tertiary filter filtration system for the City of Corona.

## Employment History

*Trussell Technologies, Inc.*
•Principal Engineer I (01/15-present)
•Supervising Engineer III (1/14-12/14)
•Supervising Engineer II (01/12 – 12/13)
•Supervising Engineer I (01/11 - 12/11)
•Senior Engineer III (1/09 - 1/10)
•Senior Engineer I, (11/08 – 12/08)
*University of California at Berkeley*
•Graduate Student Researcher, University of California, Berkeley (2003-2008)
•Graduate Student Instructor, University of California, Berkeley (2005)

## Project Experience (Selected Projects)

**WQTS / East Bay Municipal Utility District (EBMUD)**

Sobrante and Upper San Leandro Water Treatment Plants Ozone Application Point Study Year: 2014

The East Bay Municipal Water District (EBMUD) was one of the pioneers in applying ozone to municipal drinking water treatment for reducing both disinfection by-products and taste & odor compounds. When EBMUD installed their existing ozonation systems at the Sobrante and Upper San Leandro Water Treatment Plants (WTPs) in the early 1990's, the most common practice was to add ozone to the settled water prior to filtration. More than twenty years later, EBMUD is in the planning phase of replacing the aging ozone generators with new high-efficiency ozone generators, and replacing the existing air feed systems with liquid oxygen systems (LOX). As part of this project, EBMUD is re-evaluating the ozone addition point to determine if a change from intermediate ozonation to pre-ozonation is in the District's best interest. To make this decision, EBMUD hired Trussell Technologies (as a sub-consultant to WQTS) to provide technical expertise, to review the situation, and make a recommendation for the future ozone siting.

Trussell Technologies developed a thorough understanding of the needs and drivers for ozone for both Sobrante and Upper San Leandro WTPs through a review of historical data, reports, and design documents, as well as through site visits, interviews, and workshops with plant staff. Trussell Technologies then performed an independent evaluation of the benefits and challenges of each siting location, including the implications of the siting to the product water quality, plant capacity, operational difficulty, and cost. The evaluation was performed considering the experiences at other ozonation facilities (representing both pre-ozonation and intermediate ozonation), technical literature, and previous project experiences. Trussell Technologies and WQTS presented their findings to EBMUD along with a technical report making a final recommendation for each facility.

**Role:** *Project Engineer*

**Monterey Regional Water Pollution Control Agency**

Groundwater Recharge Project piloting

Year: 2013 – Present

To meet water supply needs in the region, the Monterey Regional Water Pollution Control Agency (MRWPCA) consulted Trussell Technologies in developing an Advanced Water Treatment (AWT) process for a Groundwater Replenishment (GWR) project and to find new, suitable source waters. Trussell Technologies devised an extensive water quality monitoring program for potential sources waters and conducted bench-scale testing to determine both the suitability of the sources for treatment and to determine the most efficacious treatment process.

After bench-scale testing, Trussell Technologies piloted specific processes of preliminary AWT treatment train, namely ozone, microfiltration, and reverse osmosis (RO), and developed a water quality sampling campaign for the pilot operation. With the operational and water quality data from the pilot, a 10% level design was developed for the whole AWT, which also included advanced oxidation (UV/AOP), and post-stabalization.

**Role:** *Project Engineer*

**City of Daly City**

Title: Tertiary Filter Capacity Evaluation and Disinfection System Predesign

Date: 2012 – present

The Daly City WTP discharges approximately 12 mgd of secondary effluent through an ocean discharge. In 2004, the plant was upgraded to enable the production of 2.7 mgd of tertiary recycled water (granular media filtration and chlorine disinfection). Demand for the recycled water quickly exceeded this rated capacity, and further upgrades to the existing facility were considered infeasible due to the confined plant footprint. Trussell Technologies is working to rerate these continuously-backwashing upflow filters (Dynasand) above the Tilte-22 limit of 5 gal/ft$^2$-min, with a goal of increasing the tertiary capacity by approximately 2 mgd tertiary. In addition, Trussell Technologies is developing a predesign of an extremely compact disinfection system capability of treating the additional water produced by the filters.

**Role:** *Project Manager*

**Kennedy-Jenks/City of Santa Cruz**

Title: Graham Hill Water Treatment Plant – Granular Media Filter Rehabilitation

Date: 2013 – present

Last upgraded in 1986, the City of Santa Cruz is in the process of rehabilitating their granular media filters, which have a rated capacity of 24 mgd. During this rehabilitation period, several improvements are being made to the to improve the filter performance (media replacement, underdrain replacement, air scour addition, trough replacement). Williams used a modeling-based approach to determine the optimal media configuration for the new filters, based on historical performance and performance goals set by the City. In addition, Williams is conducting pilot testing of various media configurations to verify the improvements and demonstrate operation at increased filtration rates.

**Role:** *Project Manager – Filter Media Expert*

**Dudek/City of Corona**

Title: Corona Tertiary Filtration Project

Year: 2011-2012

Trussell Tech was hired to provide process design for a new 4 mgd tertiary filtration system for the City of Corona Department of Water and Power. Williams was responsible for evaluating process alternatives, developing the design criteria for granular media filtration system, including: media selection, backwash design, and backwash waste treatment. Modeling of

various granular media designs were used to develop a design well-suited to the City's needs. By optimizing granular media filter design to maximize run times and treating backwash wastewater through a repurposed microfiltration system, the combined filtration process boasts a 97% recovery rate and minimizes loads on upstream process units.
**Role:** *Process Engineer*

### Santa Ana Watershed Project Authority (SAWPA)

Title: Inland Empire Brine Line Solids Formation Study
Date: 2011 – present

SAWPA manages a 73-mile pipleline that conveys 12 mgd of mixed waste from brine, domestic wastewater, commerical, and industrial dischargers. Over the past decade, formation of solids in the Brine Line have lead to more than $1M per year costs related to excess treatment and disposal charges. Trussell Technologies was hired to determined the most likely causes of the solids formation and evaluate options available for reducing the size of the problem. Trussell Technologies started with a detailed characterization of the solids present at the end of the Brine Line to determine the possible formation mechanisms. Trussell Technologies made improvements to the methods for sample collection, which corresponded with a significant reduction in the scale of the solids formation problem. The size of the problem is currently being reassessed, and Trussell Technologies is providing ongoing support and evaluation of mitigation strategies.
**Role:** *Project Manager*

### Monterey Regional Water Pollution Control Agency, City of San Jose, City of Santa Rosa, Delta Diablo Sanitation District, Los Angeles County Sanitation District

Title: Filter Loading Evaluation for Water Reuse (FLEWR) Phase II, Full-Scale Filter Study
Date: 2006 – present

Based on the findings from FLEWR Phase I (see below), the California Department of Public Health (CDPH) has allowed full-scale granular-media tertiary filtration plants to test loading rates above the Title-22 allowable limit of 5 gpm/ft$^2$. This study established a CDPH approved procedure for treatment facilities to obtain permanent exception to the Title-22 limit through demonstration of equivalent filter performance at higher loading rates. Based on this work, CDPH has rerated three granular-media tertiary facilities to a filtration rate of 7.5 gpm/ft$^2$, increasing capacity by 50% and saving more than $50M in construction costs. Williams has played a key role in this multi-plant study by designing all study protocols, analyzing all results, and preparing final reports for facilities as they complete testing.
**Role:** *Project Manager, Project Engineer, Doctoral Researcher*

### Monterey Regional Water Pollution Control Agency

Title: Filter Loading Evaluation for Water Reuse (FLEWR) Phase I, Pilot-Scale Filter Study
Date: 2003-2006

Due to an inadequate understanding of the effect loading rate has on tertiary filter performance, California's Water Recycling Criteria (Title-22) limit the maximum allowable filter loading rate to 5 gpm/ft$^2$. Because filtration is often the limiting process in terms of treatment capacity, increasing the allowable loading rate would free many California water reclamation facilities to increase their production of recycled water, without the need of costly capital additions. This pilot-study developed a better understanding of the role loading rate plays on tertiary filter performance and identified the factors necessary to achieve equivalent treatment at higher rates. As part of his doctoral research, Williams was integral to the success of this project by designing the pilot facility, overseeing pilot construction and operation, analyzing all results, and participating in discussions with the California Department of Public Health.
**Role:** *Doctoral Researcher*

### WateReuse Foundation

Title: Reclaimed Water Desalination Technologies: Establishing Nitrification Reliability Guidelines for Water Reuse
Date: 2011 – Present

This study addresses regulatory limitations on chlorine disinfection, through establishing guidelines for nitrification reliability. When the

current California Water Recycling Criteria were developed, nitrification was not considered a reliability enough process to ensure ammonia would be consistently removed from the product water. As a result, disinfection CT values for recycled water are based on the inactivation rates of less reactive chloramines. The ability of water reuse facilities to reliably nitrify has not been documented to the satisfaction of the California Department of Public Health, and nitrification reliability features in place before water reuse regulations will differentiate between chloramine and chlorine disinfection. This project involves the coordination of eight recycled water facilities to document reliability of nitrification in various secondary biological processes, evaluate various online low-range ammonia analyzers as tools for continuous monitoring, and develop a guidance document for ensuring reliable nitrification such that free-chlorine disinfection CT values can be applied to recycled water.
**Role:** *Principal Investigator*

**Vallecitos Water District**
Title: Meadowlark Operations
Year: 2009 – 2010
Vallecitos Water District owns and operates the Meadowlark Water Reclamation Facility, which is capable of treating up to 5 mgd of wastewater to produce recycled water for local customers. Historically coliform hits have been an issue at Meadowlark. Trussell Tech assisted with process modifications to reduce chemical consumption and alleviate the coliform issues. Trussell Tech diagnosed multiple issues with the chlorination, filtration, and primary treatment systems contributing to the problem. Trussell Tech was able to cut chlorine consumption by more than 50% with a new chlorine injection system, while simulateously solving the coliform exceedence problems. In addition, Trussell Technologies implemented strategies to minimize particle sloughing (shown to be the cause of turbidity spikes and particle breakthroughs), and ease coagulant dosing by maximizing aeration basin efficiency for better up stream turbidity removal.
**Role:** *Project Engineer*

**Fallbrook Public Utilities District**
Title: Tracer Study and CDPH Review
Date: 2009
Trussell Technologies was hired by Fallbrook PUD to evaluate the chlorine contact basin capacity of the Fallbrook Water Reclamation Plant, in compliance with a request from the California Department of Public Health. Trussell Tech developed a plan, executed the tracer study tests using the slug dose method, analyzed the result, and prepared a draft report summarizing the results for the District and CDPH. As a result of this study, CDPH approved a new capacity rating and chlorine equation for the Water Reclamation Plant. Williams was responsible for design the plan, executing the study, and coordinating with CDPH.
**Role:** *Project Engineer*

**San Elijo Joint Powers Authority**
Title: Recycled Water Improvement and Expansion
Date: 2008 - present
The San Elijo Water Reclamation Facility is in the process expanding their recycled water capacity and improving the water quality by adding a partial RO system to lower the product water salinity. Trussell Technologies, Inc. was hired by the Joint Powers Authority to develop a conceptual design for the RO treatment plant, evaluate the capacity of the existing recycled water system, and study the existing chlorine contact basin to determine if the actual capacity could be increased. Trussell performed a tracer study on the chlorine contact basin to determine the actual hydraulic capacity and analyzed tracer study data to prepare reports to Regional Water Quality Control Board and CDPH. As a result of this study, the chlorine contact basin was rerated to a larger capacity, such that no additional disinfection was needed in association with the MF/RO expansion.
**Role:** *Project Engineer*

**WateReuse Foundation**
Title: Reclaimed Water Desalination Technologies: A Full-Scale Performance and Cost Comparison between EDR and MF/RO
Date: 2009 - 2010
Many water reuse facilities are required to reduce the product water salinity and RO membranes have been the predominate technology used to remove salt removal in recycled water. However, because of its lower capital cost, Electrodialysis Reversal (EDR) is often proposed as an alternative to RO, but rarely actually selected (only used for reuse by two plants in US), because the actual life-cycle costs for a reuse plant are unknown. Trussell Technologies, Inc. compared the actual capital and O&M costs of EDR and RO membranes facilities used to remove salt from recycled water. The final report from this project serves as practical guide to water reuse utilities to select of the most appropriate and economical desalting technology based on the specifics of their plant.
**Role:** *Project Engineer*

**RMC/LADWP Recycled Water Master Plan**
Title: Assessment of Effects of Temperature on Recycled Water Treatment Processes
Date: 2009 – 2010
In their efforts to develop a recycled water master plan, the City of Los Angeles looked for additional reuse opportunities by evaluating tertiary treatment of high-temperature secondary water that had been used as cooling water. This high-temperature water presented unique challenges for conventional tertiary treatment. An evaluation of the impacts of temperature on all recycled water treatment processes was conducted, considering both the positive and negative effects of temperature on treatment performance, operations, maintenance, energy use, and equipment life. Williams' responsibilities included developing the technical approach, evaluating technologies, and project management.
**Role**: *Project Manager*

**RMC/LADWP Recycled Water Master Plan**
Title: Satellite Reuse Technology Assessment
Date: 2009-2010
In their efforts to develop a recycled water master plan, the City of Los Angeles looked to maximize their opportunities for reuse through satellite water treatment facilities. This project focused on evaluating all treatment technologies that had potential for use in satellite facilities, considering performance, cost, footprint, and reliability. Responsibilities included evaluating technologies, technologies selection, and partial project management.
**Role**: *Project Engineer*

**RMC - Marina Coast Municipal Water District**
Title: Desalination Plant Predesign and Permitting
Date: 2008 - 2011
After decades of unsustainable pumping of fresh groundwater supplies, the fresh groundwater supply below the Marina, CA coastline was destroyed by seawater intrusion. An RO drinking water treatment plant was being developed to desalinate this saline groundwater and supply a sustainable potable water source for the community. The production capacity of the desalination facility will be 10 mgd expandable to 14 MGD. Trussell Technologies, Inc was hired by RMC to prepare a conceptual design of the plant, and assist with the process selection, water quality goals, predesign, and the Department of Public Health permitting, including the preparation of the water quality monitoring plan.
**Role**: *Project Engineer*

**West Yost Associates – Davis-Woodland Water Supply Project Partners**
Title: Davis-Woodland Water Supply Project Pesticide White Paper
Date: 2010 – 2011
Working with the City of Davis, City of Woodland, and UC Davis to develop a regional water supply project that diverts Sacramento River Water to meet the potable water supply needs of the Davis-Woodland communities. The proposed surface water treatment plant will have the capacity to treat a proposed 53 mgd of river water. Responsibilities included developing approach to determining pesticides

of concern, reviewing water quality results, and project management.
**Role:** *Project Manager*

**West Yost Associates – Davis-Woodland Water Supply Project Partners**
Title: Davis-Woodland Water Supply Project Predesign and permitting
Date: 2009 – 2012
The City of Davis, City of Woodland, and UC Davis joined together to develop a regional water supply project that diverts Sacramento River Water to meet the potable water supply needs of the Davis-Woodland communities. A surface water treatment plant with the capacity to treat 53 mgd has been proposed treat the river water. Trussell Technologies, Inc. was hired by West Yost Associates to assist in the water supply permitting, preparing the water quality monitoring plan, lead coordination with the California Department of Public Health, and to develop a predesign for the proposed facility.
**Role:** *Project Engineer*

***RESUMÉ***

**BAHMAN SHEIKH, PH.D., P.E.**

Water Resources and Water Recycling Specialist

*Distinguished Fellow, Center for Integrated Water Research, University of California, Santa Cruz*

http://www.bahmansheikh.com ♦ Bahman.sheikh@gmail.com

## EXPERIENCE SUMMARY

Bahman Sheikh has over 30 years of domestic and international experience in research, planning, and design of water resources projects, specializing in water conservation, reclamation, reuse, and recycling (beneficial reuse of treated wastewater). His career began as a university professor, teaching courses in water quality for various irrigation applications. Sheikh's academic career was followed by consulting, technical investigations, planning, and design of water resource facilities. Sheikh's water recycling experience includes service in the public sector with goal-setting, project planning, regulatory liaison, public outreach, and implementation of public policy programs. The focus of much of this work has been on public health and safety from the microbiological and chemical quality of water used for irrigation and other applications. He has served clients in 21 countries, including Peru, Bonaire, Mexico, South Korea, Australia, Saudi Arabia, Egypt, India, Jordan, Kuwait, UAE, Syria, Bahrain, Morocco, and Tunisia.

Bahman Sheikh has extensive experience in all aspects of water resources management, water use patterns and promotion of water use efficiency, water reclamation, recycling, and reuse, including the technical and regulatory issues, water quality, program management, alternatives analysis, feasibility studies, and planning for long-term development of water recycling in large and small communities. He conceived, planned, and conducted major long-term pilot studies of pioneering water recycling programs in Monterey County, California, and in the City of Los Angeles, demonstrating the safety of regulated use of highly treated and disinfected reclaimed water.

Bahman Sheikh is a member of the Research Advisory Board of the National Water Research Institute. He served on the Board of Directors of WateReuse Association and WateReuse Foundation. Highlights of Bahman Sheikh's specialized experience are briefly listed below:

| Domestic | International |
|---|---|
| **Denver Water—2014-Ongoing**<br>• Preparation of documentation and presentations to provide the basis for the Colorado public health and water quality assurance authorities to consider allowing more widespread uses of highly-treated recycled water, especially for irrigation of edible crops.<br><br>**Monterey Regional Water Pollution Control Agency**<br>• Currently serving on a consultant team planning a potable reuse project involving injection | **Jaipur, Pune, Faridabad, India 2012-2013**<br>• Through subcontract with DAI: Prepared customized water use survey instruments for residential, industrial and commercial sectors of the three cities and trained local interviewers who completed hundreds of individual user profiles. ## Domestic

of highly treated recycled water into the Seaside Aquifer, as part of a multi-faceted water supply plan for the future of Monterey Peninsula.

**San Francisco Public Utilities Commission—2011-Ongoing**

- As joint-venture partner with Kennedy/Jenks Engineers, prepared master plan for development of recycled water project on the Eastside of San Francisco. Customers include dual-plumbed buildings prepared for switching to recycled water for toilet flushing, parks and landscapes switching to recycled water for irrigation, and other uses.

**City of San José, California—1997--Ongoing**

- Provides ongoing training for hundreds of newly assigned site supervisors for customers receiving recycled water from the SBWR network. Prevention of cross connection and backflow in dual-plumbed buildings and dual-use sites is a major component of this project.
- Provided expert consulting services throughout the two decades of development of the South Bay Water Recycling (SBWR) infrastructure. Customers of SBWR include dual-plumbed buildings using recycled water for toilet flushing—such as the new San Jose City Hall and the 49ers Levi's Stadium in Santa Clara.
- Created a mathematical model for projecting the economic impact of salinity increases in recycled water due to industrial brine discharges into the City sewers upon the customers of recycled water.
- Conducted site investigations in response to recycled water customers' concerns about water quality and landscape impacts.
- Reviewed and critiqued another consultant's study of impacts of recycled water on Santa Clara and Llagas Groundwater subbasins, with special emphasis on NDMA fate and transport.

**Santa Clara Valley Water District—2000--Ongoing**

- Currently, facilitating discussions among top managers in the District regarding future potential strategies for eventual implementation of potable reuse options—indirect and/or direct.
- Prepared a computational model to assess the impact of irrigation with recycled water over the unconfined aquifers in Santa Clara Valley, with special emphasis on salinity.

## International

ficiency Guidelines for three cities in India: Jaipur, Pune, and Faridabad.

**German Government Development and Export Fund (KFW)**

- 2003, through Dorsch Consult. Provided expertise for the design of a water reclamation and reuse treatment and distribution infrastructure for the Greater Gaza City, Palestinian Territory.
- 2005, through Dorsch Consult. Provided specialized engineering services for the design of an efficient irrigation system using recycled water for landscaping in hotels and government buildings on the Island of **Bonaire**, in the Netherland Antilles.

**United Nations Food and Agriculture Organization (FAO)**

- 2013, Provided Study Tour of exemplary recycled water projects in the United States for a select group of officials from the Saudi Arabia Ministry of Agriculture. The Study Tour spanned major water reuse sites in Florida, California, and Virginia.
- 2009, Served as technical advisor for use of recycled water (water reclaimed from wastewater, locally referred to as Treated Sewage Effluent, or TSE) in irrigated agriculture throughout the Kingdom by providing guidelines, leading training sessions.

**Barwon Water, Victoria, Australia**

- 2010-2013, Served as member of expert panel independently evaluating planning efforts toward an indirect potable reuse project to be implemented as part of a multi-pronged approach to future water supply security for the region.

**Australian National Environmental Protection Council Service Corporation**

- Peer reviewed draft of the Australian National Guidelines for Water Recycling

**Tunisia, Transfer of Recycled Water from Tunis to Southern Tunisia**

- 2009, Provided guidelines and case studies of similar transfers over long distances for use in irrigation, industry, and geothermal fields replenishment.
- 2007, Guided a group of Jordanian engineers in

## Domestic

- Facilitated discussions between the District and the City of San Jose (SBWR) regarding future form of collaboration between the two agencies for delivery of recycled water to their service areas. A forty-year agreement for joint development and operations resulted from the success of these negotiations.

**City of Chula Vista—2002**

- Investigated the feasibility and comparative costs and benefits of a large number of water demand management options, including residential water conservation, commercial and industrial measures to reduce demand, use of gray water for landscape irrigation, and water recycling.

**Marin Municipal Water District—2001**

- Investigated the comparative costs and benefits of alternative sources of water supply for the District including use of gray water, water recycling and desalination of seawater from the San Francisco Bay or from the Pacific Ocean.

**City of Los Angeles, California—1991-1996**

- Developed achievable goals and a master plan-for recycled water development that were adopted by the City Council. Provided interdepartmental liaison that enabled planning and ultimate implementation of several major water recycling projects in cooperation with West Basin Municipal Water District. Prepared policy analysis for control of salt discharges from residential water softeners into the municipal sewer system. Commissioned a city-wide survey of water softener use and salt purchase patterns of residents. Recommended adoption of an ordinance for prohibition of use of self-regenerating water softeners, which involve discharge of salts and wastage of water as brine is periodically discharged into the sewers during the regeneration cycles.
- Conducted a year-long graywater reuse pilot project at eight residential locations throughout the City of Los Angeles with monthly monitoring of soils, water, and vegetation for microbial, chemical and other characteristics.

**Monterey Wastewater Reclamation Study for Agriculture—1975-1986**

- Managed $7.2 million research and demonstration project on irrigation of raw-eaten vegeta-

## International

site visits to wastewater treatment plants in various parts of Tunisia, with an emphasis on beneficial uses of reclaimed water.

**Amman, Jordan (Subcontract with various USAID contractors)**

- 2008, through DAI, "Water Efficiency Recommendations for High Rise and High Density Developments" in the Greater Amman Municipality, developing best management practices (BMPs) for water reuse and conservation.
- 2005, through Chemonics, "Review of Aqaba Watger Demand and Expanded Evaluation of Water Resources."
- 2004, through ARD, Facilitated discussion workshops for members of Water Reuse Standards Committee from the Ministry of Water and Irrigation, Ministry of Health, and the Jordanian Institute for Standards and Metrology. These workshop sessions led to formulation of recommended water reuse standards for adoption by the government of Jordan.

**King Saud University, Riyadh, Saudi Arabia—2006-Date**

- Retained as Senior Advisor to Prince Khaled Chair for Water Research at the Department of Civil Engineering.
- Provides periodic workshops and seminars to graduate students and government officials on sustainable water policies and practices

**Arriyadh Development Authority (ADA)**

- 2000. Sheikh created a master plan for water, wastewater and reclaimed water for the City of Riyadh, Saudi Arabia, for the period to 2022 at which time the City's population would increase by 7,000,000 people.
- 2007. Assisted ADA in development of terms of reference (TOR) for bidding for implementation of water reclamation facilities (treatment, distribution, and retrofits) throughout the rapidly developing areas of the City of Riyadh.
- 2009. Oversaw and reviewed work products of other consultants engaged to prepare water recycling facilities plans for the City of Riyadh

**Kuwait Institute for Scientific Research**

- 2008, Prepared recommendations for updating of Kuwait's regulations and criteria for use of reclaimed water in agriculture, landscape irriga-

## Domestic

bles with recycled water, for over eleven years.

- Planned scientific design of field experiments to distinguish any impacts of use of reclaimed water on plants, soils, crop yield, crop quality, groundwater, and the environment.
- Published reports of findings and obtained the agreement of public health officials to permit use of the reclaimed water on raw-eaten food crops.
- Performed liaison and facilitation services among stakeholders, including farmers, public health officials, water supply agencies, and other environmental and citizen groups

**West/Central Basin Municipal Water Districts—1986-1988**

- Provided technical input into the Districts' extensive water reuse activities, analyzing alternatives, feasibility, economic viability, regulatory compliance, and funding of numerous projects.
- Participated in Districts' public outreach functions, promoting recycled water use
- Prepared the District's Urban Water Management Plan
- Conducted technical sessions for potential new customers of recycled water—golf courses, nurseries, parks, industries.

**WateReuse Association**

- Co-chair of the International Committee, working to expand the reach of the Association into the Middle East region.
- Completed a White Paper on Graywater for the Association Board of Directors' policy decision vis-à-vis inclusion of graywater in the Association portfolio.
- Completed a national training manual for site supervisors and users of recycled water.
- Prepared and updated summary of Title 22 "allowed uses of recycled water".
- Served as chairman of Public Education Committee.
- Collaborated in the preparation of an interactive compact disc for landscape users of recycled water for problem-solving and design of new landscaped irrigated with recycled water.
- Served on the video committee—"Water In An Endless Loop".
- Prepared popular brochure on Graywater—"Clear Facts about Gray Water".

## International

tion, industry, and groundwater recharge.

**United Stated Agency for International Development**

- 2006, through CDM and PA Consulting: Assisted local staffs in the cities of Nagpur and Hyderabad, India, to develop industrial water recycling and reuse programs, beginning with pilot treatment systems.
- 2003, through ARD: Developed a new framework for "Standards, Regulations, and Legislation for Water Reuse" in Jordan.
- 2004, through CDM: Prepared Chapter 8 of the USEPA/USAID Water Reuse Manual, describing international water reuse practices.
- 2003, through Chemonics: Reviewed Egyptian proposed rules for use of reclaimed water in agriculture.
- 2004, through PA Consulting: Reviewed a master plan for a swap of agricultural water with urban reclaimed water in the metropolitan Hyderabad, in the state of Andra Pradesh, India.

**The World Bank—2001**

- Prepared an extensive background document and proceedings and provided technical resource to a regional water reuse workshop for 10 countries of the Middle East and North Africa (MENA) in Cairo, Egypt.

**Jaffna Peninsula, Sri Lanka—1983**

- Developed end user water use information database and recommended water conservation policies and strategies in urban and agricultural areas of Jaffna Peninsula including the most cost-effective methods for reducing demand for water, especially during the low-rainfall seasons.

**Casablanca, Morocco. Use of Treated Wastewater Effluent for Irrigation of Early-Season Vegetables for the European Export Market**

- 1990, Prepared economic feasibility analysis of reclaiming wastewater from the Casablanca-Mohammediah areas for use for irrigation of vegetables in the suburban agricultural region, specifically for early-season export to the European market.

**Author of Chapter 6 in "Water Reuse for Irrigation" Edited by Valentina Lazarova and Akiça Bahri, CRC, 2005.**

## PROFESSIONAL HISTORY

1996-Date **Independent Water Resources and Reuse Consultant**, providing specialized services to public and private clients in their water reclamation projects. Major current and recent clients include USAID, The World Bank, Petroleum Institute of Mexico, Marin Municipal Water District, Metropolitan Water District of Southern California, Coachella Valley Water District, Las Virgenes Municipal Water District, Monterey Regional Water Pollution Control Agency, the City of San Jose South Bay Water Recycling Program, West/Central Basin Municipal Water Districts, Parsons Engineering Science, Harland Bartholomew, Harza Environmental Services, Bechtel International, ARD, Inc., City of Chula Vista, and Central Contra Costa Sanitary District. In addition to numerous projects in California, Bahman Sheikh serves clients with water reclamation projects in various countries, including the Netherland Antilles (Bonaire), Jordan, Kuwait, Saudi Arabia, Bahrain, Turkey, Peru, Tunisia, Morocco, and Egypt.

1994-1996 **West Basin and Central Basin Municipal Water Districts. Water Resources and Wastewater Reuse Policy Specialist.** In this capacity he advised the Districts' management on water policy issues, represented the Districts at various State forums, interfaced with regulatory agencies, environmental groups, community organizations, and the public, and worked with water customers and member utilities to solve issues and problems arising as the District expanded its water reclamation service area. Representing the Districts, Bahman Sheikh served on a number of Statewide committees working to manage the State's water resources more efficiently, e. g.:

- U.S. Bureau of Reclamation Executive Management Committee, overseeing the preparation of the "Southern California Comprehensive Water Reclamation and Reuse Study" with federal-local partnerships.
- State Potable Reuse Committee, convened by the Directors of the State Department of Water Resources and the State Department of Health Services to develop and foster regulatory and public acceptance for safe augmentation of potable water supplies with potable reclaimed water.
- Chair, Public Education Committee of WateReuse Association of California, planning and implementing public information and outreach programs on water reuse for the Association.

1989-1994 **City of Los Angeles. Executive Director, Office of Water Reclamation.** This Office was created within the Board of Public Works to bring into focus the City's basic goal of maximizing the reclamation of its wastewater resource. The City recognized the need for new water policy directions because of the increasing vulnerability of its sources of imported water supply. Bahman Sheikh was recruited to set near- and long-term water reclamation goals, bring together diverse decision-making bodies, help establish funding mechanisms, be a good-will ambassador to the public and to outside agencies, and prepare plans and strategies to achieve the City's basic goal. Policy analysis, legislative recommendations, funding and financing, interagency coordination, and interdepartmental liaison were important aspects of Bahman Sheikh's responsibilities.

Specific goals recommended by Bahman Sheikh were adopted as City goals by the Council and by the Board of Water and Power Commissioners. Based on these adopted goals, a number of water reclamation projects have been developed and are now being implemented. An important function of the Office was coordinating the water reuse activities of the major water purveyor (LADWP) and wastewater management entity (Department of Public Works) in the City, and establishing an outreach program to make the public aware of the safety and desirability of water reuse in all its forms. He designed and directed a yearlong pilot project demonstrating the safety of using gray water systems for residential landscape irrigation. The results of this pilot project were the technical basis for new regulations adopted Statewide for residential gray water use. He provided testimony at numerous local and State hearings before a variety of boards regarding reclaimed water policy.

The Office of Water Reclamation worked closely with the Mayor's Office, the City Council, and the Boards of Commissioners of Public Works and Water and Power. Examples of initiatives presented to policy makers were the gray water legalization policy and ordinances to control water softeners and to require dual plumbing in all new high-rise construction. The resultant policies caused implementation of several water reclamation projects. Bahman Sheikh represented the City of Los Angeles at numerous statewide water forums, including the following:

- Chair, Regulatory Committee of the WateReuse Association of California, working with State Department of Health Services to revise regulations governing water reuse.
- Member, Bay Delta Oversight Council (BDOC) Technical Advisory Committee on Water Supply.
- Chair, Survey Committee of the WateReuse Association of California. Prepared the 1993 estimate of Statewide water reuse potential in cooperation with the State Department of Water Resources, Metropolitan Water District of Southern California, San Diego County Water Authority, and numerous other retail and wholesale water purveyors.
- Member, California Ad-Hoc Gray Water Committee. Prepared Appendix J to the State Plumbing Code to allow individuals to use gray water in residences, under special restrictions, to protect the public health and prevent backflow into the community water supply.
- Member, DWR/DOHS-sponsored committee to develop dual plumbing standards for reclaimed water service inside high-rise buildings for toilet flushing and other non-potable water uses.
- Member, Legislative Committee of WateReuse Association of California, preparing and supporting legislation to facilitate and expand uses of reclaimed water in the State.
- Member, U.S. Bureau of Reclamation Executive Management Team for the Southern California Comprehensive Water Reclamation and Reuse Study.

1987-1989 **CH2M HILL. Civil/Environmental Engineer.** Directed and managed major water reuse projects and contributed senior review and specialized expertise to the firm's water supply and reclamation projects. Examples of his contributions include:

- **City of Ankara, Turkey:** participated in developing a master sewerage plan for the capital City of Ankara, Turkey, population 4 million, where he directed the modeling of the wastewater collection system for the entire City.
- **City of Los Angeles:** Participated in the preparation of the City's Advanced Planning Report by leading the water supply shortfall projections and analyses that resulted in recommendations for full utilization of the City's reclaimed water potential. The City's APR provides for wastewater management planning for the next 100 years and the City's needs for major wastewater and water reclamation infrastructure facilities.
- **City of Santa Rosa:** Analyzed nutrient balance in two basins proposed to receive reclaimed water for irrigation of fodder crops.
- **San Jose/Santa Clara Treatment Plant:** Analyzed opportunities for reclamation of the effluent from the plant and recommended a phased approach including irrigation of parks, industrial cooling, recharge into groundwater aquifers, and dilution of Leslie Salt Company's bittern before discharge.

1970-1987 **PARSONS Engineering-Science. Manager.** He was Project Director and oversaw the work of several project managers and engineers performing assignments on a variety of environmental engineering projects for diverse private and public sector clients. His projects are briefly highlighted below*:*

- **Areawide Water and Sewerage Master Plans:** Managed comprehensive areawide water and sewerage planning studies for mountainous, desert, and metropolitan areas of San Bernardino, Napa, and El Dorado Counties under a Farmers Home Administration planning grant program.

- **Monterey Regional Water Pollution Control Agency:** Bahman Sheikh was responsible for the conception, direction, and execution of the 11-year pilot field demonstration project for Monterey Regional Water Pollution Control Agency, investigating the feasibility of irrigating raw-eaten food crops with disinfected, tertiary-treated reclaimed water. This project, known as the Monterey Wastewater Reclamation Study for Agriculture (MWRSA), attracted worldwide interest and has been reported at many conferences and professional publications. Bahman Sheikh led MWRSA from its inception in 1976 continuously through the publication of its final report in April 1987. His effective communication of the technical intricacies of water reuse to the local farmers, local health authorities, and a score of different governmental agencies was crucial to the successful completion of the project. Large-scale irrigation with recycled water on 12,000 acres in the northern Monterey County is now routine, thanks in part to the success of MWRSA, credibility of its results, and the need for sources of additional water supply in the region.

- **Northglenn-Denver, Colorado:** Performed a water exchange study for Northglenn, Colorado, investigating use of reclaimed Denver wastewater for irrigation of sugar beets in exchange for rights to ditch waters to be diverted for municipal supply.

- **Las Palmas Ranch, Salinas, California:** Directed the evaluation of various irrigation systems, including drip irrigation, for application on a 60-acre hillside for reuse of treated municipal effluent from Las Palmas Ranch, a proposed housing development near Salinas, California.

- **Environmental Impact Studies:** Was responsible for development of Environmental Impact Reports and Statements on a variety of projects including land application of effluents and wastewater biosolids, solid waste disposal, and wastewater treatment. Bahman Sheikh performed erosion, sediment transport, irrigation, and urban runoff investigations as part of a comprehensive water quality management study of the James River Basin in Virginia.

1967-1970 **University of Shirz, Assistant Professor.** Bahman Sheikh taught technical courses in water systems design, water resources and supply management, water utility administration, irrigation, soils, hydrology and hydraulics at the University of Shiraz, College of Agriculture (in Iran). He designed and supervised construction of a hydraulics teaching and research laboratory at the field campus of the College.

## ACADEMIC ACTIVITIES

In recent years, Bahman Sheikh has taught classes—as guest lecturer and seminar presenter—in topics related to California water, at several institutions of higher learning, including:

- Department of Civil & Environmental Engineering, Woods Institute for the Environment, Stanford University
- Department of Civil Engineering University of California, Davis
- Public Policy Program at Pomona College
- School of Architecture at the University of Southern California
- Environmental Engineering Program at the University of Southern California
- Environmental Engineering at California State University at Long Beach
- Occidental College Faculty Seminar
- Extension Service of the University of California at Davis, Courses in Legal and Regulatory Water Issues
- Water Resources Short Course at UCLA for Water Officials of the Government of Thailand

## INTERNATIONAL CONSULTING:

Over the past two decades, Bahman Sheikh has completed numerous overseas missions of varying duration. Typically, he provides expert and specialized consulting services in water resource management, wastewater treatment, water reuse and related topics, to governmental agencies in countries including Mexico, Peru, South Korea, Sri Lanka, Turkey, Syria, Bahrain, Tunisia, Morocco, and most recently in India, Egypt, Jordan, Kuwait, United Arab Emirates, and Saudi Arabia. Funding agencies for these projects are the World Bank, USAID, Asia Development Bank, and the local government agencies.

## EDUCATION

1967, Ph.D., Soil Physics (Soil-Water Relations), University of California, Davis

1964, M.S., Irrigation (Water Science and Engineering), University of California, Davis

1962, Pomona College (Interdisciplinary Studies in Liberal Arts), Claremont, CA

1957, B.Sc., Agricultural Engineering, American University of Beirut, Lebanon

## AWARDS AND HONORS

Resolution of Appreciation in recognition of 27 years of service from Board of Directors, Monterey Regional Water Pollution control Agency, March 29, 2004.

Outstanding Service Award, WateReuse Association, 2002

President's Award of Appreciation, WateReuse Association, 2002

Appointed to the Board of Directors of WateReuse Research Foundation, 2001, served until 12/2007.

Appointed to the Research Advisory Board of National Water Research Institute, 1995.

Recognized by City of Los Angeles City Council for "efforts and accomplishments," 1994

Recognized by City of Los Angeles Board of Public Works for "vision and commitment," 1994
Elected to Board of Directors, WateReuse Association, 1993, served until 2002.
Integrated Resource Management Award, Water Policy Conference III, 1993
Outstanding Service Award, WateReuse Association of California, 1991

## REGISTRATION

Professional Engineer, Civil, California: C 26633

## PROFESSIONAL MEMBERSHIPS

WateReuse Association
American Water Works Association
Water Environment Federation
California Water Pollution Control Association
National Water Research Institute, Research Advisory Board

## PUBLICATIONS AND PRESENTATIONS:

"Graywater's Future Role in Integrated Water Management Planning", Scheduled for presentation at the IWA Efficient 2011 conference at Dead Sea, Jordan, March, 2011.

"Is Graywater Another Flavor of Water Reuse?", Presented at WateReuse Association Symposium 25, Washington, D. C., September 2010.

"Terra Linda Demonstration Garden for Recycled Water-Irrigated Landscapes in Marin County", prepared for Marin Municipal Water District, June 2010.

"Graywater White Paper", prepared for WateReuse Association Board of Directors, April 2010.

"Maximizing Filtration Capacity for Production of Tertiary Recycled Water", presented at WateReuse Association Symposium 24, Seattle, Washington, September 2009.

"Recycled Water—Fit for the Use", presented at WEFTEC 2008 Workshop on Water Reclamation and Reuse: The Big Picture: Reclaimed Water as a Water Resource, Chicago, Illinois, October 18, 2008.

"Future Potential for Recycled Water", presented at WateReuse Association Symposium 22, Tampa, Florida, September 2007.

"Socioeconomic Aspects of Wastewater Treatment and Water Reuse", presented at EMWater (**E**fficient **M**anagement of **W**astewater) Regional Conference in Amman, Jordan, October 2006.

"Higher Filter Loading Rates for Greater Water Reuse Capacity", presented at WEFTEC 06, Dallas, Texas, October 2006

"National Training Manual for Commercial Recycled Water Users", presented at the 21st Annual WateReuse Association Symposium, Hollywood, California, September 2006.

"A Scientific Basis for Regulating Filter Loading Rate for Production of Recycled Water in California", presented at the 21st Annual WateReuse Association Symposium, Hollywood, California, September 2006.

with Ken Tanji, "A Landscape Guide For Irrigation With Recycled Water", presented at the 21st Annual WateReuse Association Symposium, Hollywood, California, September 2006.

"Site Supervisor Training Manual: for Users of Reclaimed Water", prepared for and published by WateReuse Association, September 2006.

"U.S. and International Perspectives on Recycled Water Disinfection", presented at the 2006 California Section Annual Conference, Bridging the Gap with Recycled Water, March 12-14, 2006, San Francisco.

"Filter Loading Evaluation for Water Reuse" Presented at WateReuse Association California Section 2005 Annual Conference in San Diego on February 28, 2005.

"Institutional Requirements in California and Florida for Implementation of Water Recycling/Reclamation Projects", Presented at WateReuse Symposium XIX, Phoenix, Arizona, September 21, 2004.

"Water Reuse: International Perspectives and Rationale for Hyderabad", presented at Confederation of Indian Industry, Hyderabad, India, September 14, 2004.

"Water Recycling Projects in California: Opportunities and Challenges", presented at 2004 Annual Conference of Victorian Farmers Federation in Melbourne, Australia, July 14, 2004

"Impact of Institutional Requirements on Implementation of Water Recycling / Reclamation Projects", presented at the 2004 Water Sources Conference in Austin, Texas, January 11-14, 2004.

"Indirect Potable Reuse through Groundwater Recharge and Surface Water Augmentation: The Gold Standard of Water Recycling in California", invited keynote presentation at the National Water Recycling in Australia Conference, September 1-2, 2003, Brisbane, Australia.

"Efficacy of Pathogen Removal at Full-Scale Operational Water Reuse Facilities in Monterey, California", presentation at WateReuse Symposium XVIII, September 7-10, 2003, San Antonio, Texas.

"Rules and Regulations/Guidelines for Water Reuse" Presentation at MED-REUNET Seminar, September 25-26, 2003, Izmir, Turkey.

"Water Reclamation World-Wide: Revisions to the International Guidelines", presented to Third World Water Forum, USAID-Sponsored Session on Update of Water Reuse Guidelines, March 16, 2003, Kyoto, Japan.

"Ethical Dilemmas in the Water Cycle in the Middle East and North Africa" presented to Third World Water Forum, San Francisco Public Utilities Commission-Sponsored Session on Ethics in Water Management, March 19, 2003, Kyoto, Japan.

"Comparing and Contrasting Benefits and Costs of Water Use Efficiency Measures in Marin County and in Chula Vista", presented at CALFED Science Conference, January 2003, Sacramento, California.

"Comparing the Costs and Benefits of Water Recycling Options with Seawater Desalination and Gray Water", presented September 10, 2002, at WateReuse Association Symposium XVII, Orlando, Florida.

"Economic Impacts of Salt from Industrial and Residential Sources", presented at AWWA-WEF Joint Water Resources Conference, "Reuse, Resources, Conservation", January 2002, Las Vegas, Nevada.

"Building Water Conservation into New Homes in Chula Vista, California", presented at AWWA-WEF Joint Water Resources Conference, "Reuse, Resources, Conservation", January 2002, Las Vegas, Nevada.

"Reclaimed Water: Benefits to Society Beyond Water Resource Value In Dry Regions of the World", presented to The First International Conference on Economical and Social Uses of Water in Arab Countries, June 18-21, 2001, Beirut, Lebanon.

with Anderson, J. *et al.*, "Climbing the Ladder: A Step-by-Step Approach to International Guidelines for Water Recycling" presented at the 1st World Congress of the International Water Association (IWA), Paris, France, July 3, 2000.

"Salt in Recycled Water: Agricultural and Landscape Limitations", presented at WateReuse Workshop on Salts In the Brine Stream, held in Phoenix, Arizona, March 29, 2000.

"Riyadh, Kingdom of Saudi Arabia: A Vision of 2021: Introducing Water Reuse to A World Capital", Presented to Water Reuse 2000, Joint AWWA-WEF Specialty Conference to be held in San Antonio, Texas, January 30-February 2, 2000.

"The Importance of Reclaimed Water for Landscape Irrigation in the Arid Zone", keynote address to the First International Conference on Greenery and Environmental Beautification in Arid Zones", Sponsored by Kuwait Institute for Scientific Research, Kuwait City, November 20-24, 1999.

"Lessons From Abroad: Water Recycling Global Perspectives", presented at Symposium XIV WateReuse Association, Long Beach, California, September 15, 1999.

with NWRI writing team, "The Value of Water: Recognizing and Using the Full Potential of Your Water Supply", National Water Research Institute, Fountain Valley, California April 1999

"Sustainable Use of Water, California Success Stories", Advisory Committee Member to Pacific Institute for Studies in Development, Environment, and Security, Oakland, January 1999

"Hygienic Evaluation of Reclaimed Water Used To Irrigate Food Crops—A Case Study", Conference Proceedings, Advanced Wastewater Treatment, Recycling and Reuse, 2nd International Conference, IAWQ, Milan, Italy, September 14-16, 1998.

"Tertiary Water Food Safety Study", report to the Monterey County Water Recycling Projects' Water Quality and Operations Committee, August, 1998.

"Accounting for All the Benefits of Water Recycling" with Eric Rosenblum, Steve Kasower and Earle Hartling, Proceedings, Water Reuse '98, a joint specialty conference of WEF and AWWA in Orlando, Florida, February 1-4, 1998.

Chapter 6, Public Information Programs, in joint publication of WEF and AWWA, "Using Reclaimed Water to Augment Potable Water Resources", pp. 191-233, February 1998.

Chapter 17, Tertiary Reclaimed Water for Irrigation of Raw-Eaten Vegetables, in "Reuse of Wastewater" edited by Prof. Takashi Asano, pp. 779-825, June 1998

"Resolving Water Quality Concerns In Irrigation of Pebble Beach Golf Course Greens with Recycled Water", in Proceedings of the Water Environment Federation 70th Annual Conference (WEFTEC'97), pp. 187-194, Chicago, Illinois, October 18-22, 1997.

"International Practices In Water Reuse", in Proceedings of the Water Environment Federation 70th Annual Conference (WEFTEC'97), pp. 281-284, Chicago, Illinois, October 18-22, 1997.

with Brock McEwen of CH2MHill and Tom Richardson of Montgomery Watson, "Indirect Potable Reuse: State of the Art", presented to the Water Environment Federation Specialty Conference on Beneficial Reuse of Water and Biosolids, Marbella, Spain, April 6-9, 1997.

"An Informed Public Favors Water Recycling" presented to the Florida Section/AWWA Specialty Conference, Maitland, Florida, November 13-15, 1996.

with Eric Rosenblum, City of San Jose South Bay Water Recycling, "Environmental Influences behind Water reclamation" presented to the Florida Section/AWWA Specialty conference, Maitland, Florida, November 13-15, 1996.

"A Preview of the WEF/AWWA Guidance Manual on the Use of Reclaimed Water to Augment Potable Water Resources", presented to WEFTEC'96, Water Environment Federation 69th Annual Conference, Dallas, Texas, October 5-9, 1996.

"Global Perspectives on Water Reuse" , presented to the Pacific Northwest Pollution Control Association, Seattle, Washington, May 17, 1996.

"Obstacles of Reuse Customers and their Resolution", presented to the Pacific Northwest Pollution Control Association, Seattle, Washington, May 17, 1996.

"Outreach and Public Education for Water Reuse" presented to Water Reuse '96 a special conference co-sponsored by WEF and AWWA, San Diego, February 25, 1996.

"The Monterey Study—Agronomic Issues", presented to the California Irrigation Institute's 34th Annual Meeting, Sacramento, California, February 2, 1996.

"Uses of Recycled Water: Opportunities and Obstacles", presented to the '95 Statewide Conference of the Association of Environmental Professionals, San Jose, California, July 15, 1995.

OWR NEWS, quarterly newsletter of the City of Los Angeles Office of Water Reclamation, was published regularly from 1990 through 1994, to communicate with City decision makers and the public, expanding public awareness of water recycling through dissemination of news and general information about the safety and necessity of uses of reclaimed water.

"Future Water Recycling Potential in Southern California," presented to the American Society of Civil Engineers Annual Meeting in Denver, May 23-26, 1994.

"Status of Present and Future Water Recycling in California," presented to the Joint AWWA/WEF Water Reuse Symposium, Dallas, Texas, February 27-March 2, 1994.
